Remedial Investigation Report for Waste Area Grouping 27 at the Paducah Gaseous Diffusion Plant Paducah, Kentucky

Volume 2 of 4
Appendices A through F

June 1999

CLEARED FOR PUBLIC RELEASE

E03199902 6ATL / Paducah Covers 2.FH8

DOE/OR/07-1777/V2&D2
PRIMARY DOCUMENT

Remedial Investigation Report for Waste Area Grouping 27 at the Paducah Gaseous Diffusion Plant Paducah, Kentucky

Volume 2 of 4. Appendices A through F

Date Issued—June 1999

Prepared by
CH2M HILL, Inc.
Paducah, Kentucky
under General Order 18B-99345C

for the
U.S. Department of Energy
Office of Environmental Management

Environmental Management Activities at the
PADUCAH GASEOUS DIFFUSION PLANT
Paducah, Kentucky 42002
managed by
BECHTEL JACOBS COMPANY LLC
for the
U.S. DEPARTMENT OF ENERGY
Under contract DE-AC05-98OR22700

VOLUME 1

Boring 001-180

Project: *Paducah Gaseous Diffusion Plant Wag 27 RI*	Coordinates: *E, N*
Location: *Paducah, KY*	Geologist: *R. McComb*
Started at *on 6/2/98*	Surface Elevation: *373.50 feet msl*
Completed at *on 6/9/98*	Depth to Groundwater: *NA feet bgs* Measured: *NA*
Drilling Method: *Reverse Air Rotary*	Groundwater Elevation: *NA feet msl*
Drilling Company: *Miller Drilling*	Total Depth: *106.5 feet*

GEOLOGIC DESCRIPTION	ELEV. (ft-msl)
Clay, same as above	
Gravel (70%) poorly sorted, fine to coarse grained angular to round, cherty with some quartz; sand (30%), medium to coarse grained, angular to round, cherty with some quartz, brownish yellow (10YR6/8)	316.5

Boring 001-180

re: WAG 27 - Remedial Investigation / Feasibility Study
Paducah Gaseous Diffusion Plant
McCracken Co., Kentucky

Dear Sir:

With this letter we are submitting a computer printout of the coordinate list of proposed bore hole locations and as-built locations for the above referenced project.

I have reviewed the enclosed information and have found it to be true and accurate to the best of my knowledge and belief.

If you have any questions, please do not hesitate to call.

Respectfully Submitted,

David H. Dummer, Jr., PLS
President

RE: Data Transmittal of the CPT/DPT Investigation
at the Paducah Gaseous Diffusion Plant
R.E. Wright Project No. 01-1408-00-1502-000

Dear Mr. Short:

R.E. Wright Environmental, Inc. (R.E. Wright) is pleased to submit this data transmittal to Miller Drilling Company (MDC) documenting the results of the Cone Penetrometer Test (CPT) investigation performed by R.E. Wright at the Paducah Gaseous Diffusion Plant (PGDP) located in Paducah, Kentucky. R.E. Wright performed this investigation at the request of Mr. Mark Herndon of MDC.

FIELD ACTIVITIES

Field activities occurred from February 19 through March 18, 1998. R.E. Wright mobilized its Cone Penetrometer Test (CPT) rig and crew to the site to perform CPT borings and continuous soil borings for evaluation of subsurface soil conditions at three solid waste managment units (SWMUs). All CPT and soil boring locations were previously designated by a representative from CH_2M Hill.

R.E. Wright utilized a 10 ton electronic subtraction cone manufactured by Hogentogler & Co., Inc. to perform the Cone Penetration Tests (CPTs). The CPT consists of pushing the cone into the ground at a constant rate of 2 centimeters per second. Measurements of tip bearing stress or resistance (Qc), sleeve friction (Fs), inclination (I), and pore pressure (u) are recorded at 5 centimeter intervals during the test to provide a nearly continuous stratigraphic log and interpretative Standard Penetration Test (SPT) N values. The data are transmitted as analog voltage signals via a cable (inside a rod string) to a computer data acquisition system located on the CPT rig. All CPTs are performed in accordance with ASTM standard (D5778) and are attached as appendix B.

The CPT crew utilized the Geoprobe® macro-core sampler to collect soil samples from the soil borings. The macro-core sampler is approximately 4 feet in length, and is lined with standard Geoprobe® acetate liners to preserve sample integrity. The sampler is equipped with a stainless steel cutting shoe. As the sampler is advanced the cutting shoe cuts through the subsurface forcing soil to enter the sampler. The sampler is retrieved and the acetate liner tube is removed from the sampler. The sampler is finally reassembled with a new acetate liner and a clean cutting shoe to collect the next macro-core.

The CPT operator presented the retrieved acetate lined soil samples from each boring to CH_2M HILL's field representative directly in the acetate liners from each boring location. The soils were logged and field screened by a represantative from CH_2M HILL.

RESULTS OF FIELD ACTIVITIES

R.E. Wright performed a total of 35 soil borings in SWMUs 196 and 01 with target depths of 10 feet below below grade (BG). Terminal depths and locations of borings are presented in Table 1.

R.E. Wright also performed 13 CPTUs in SWMUs 01 and 196, and at building 720. Actual depths and locations of the soundings are presented in Table 2. The CPTU logs and graphs are attached as Appendix A. The soil behavior type classification used in CPT stratigraphic interpretation is from Robertson *et al.*, 1986, a copy of which is included with the logs.

R.E. Wright appreciates the opportunity to provide CPT services to MDC. Please contact us if you have any questions or comments concerning the information presented herein.

Respectfully submitted,

R.E. WRIGHT ENVIRONMENTAL, INC.

2	SWMU-720-018	24.9
3	SWMU-720-018A	23

*Note: CPTU-720-012 suffered a loss of data between 8.4 feet and 10.5 feet due to a malfunctioning headload switch.

CPT LOG DEFINITIONS

The following definitions are provided in the *Operating Instructions Electronic Cone Penetrometer*, by Hogentogler & Co., Inc., February 1995 to assist in the interpretation of the retrieved CPT stratigraphic logs.

- *Qc-Tip Resistance*: This is the measured resistance on the 60 degree, ten square centimeter tip of the cone, printed in terms of pressure; force divided by unit area.

- *Fs-Local Friction*: This is the measured resistance, due to soil friction, on the 150 square centimeter friction element located directly above the tip. Fs is also printed in terms of pressure; force divided by unit area.

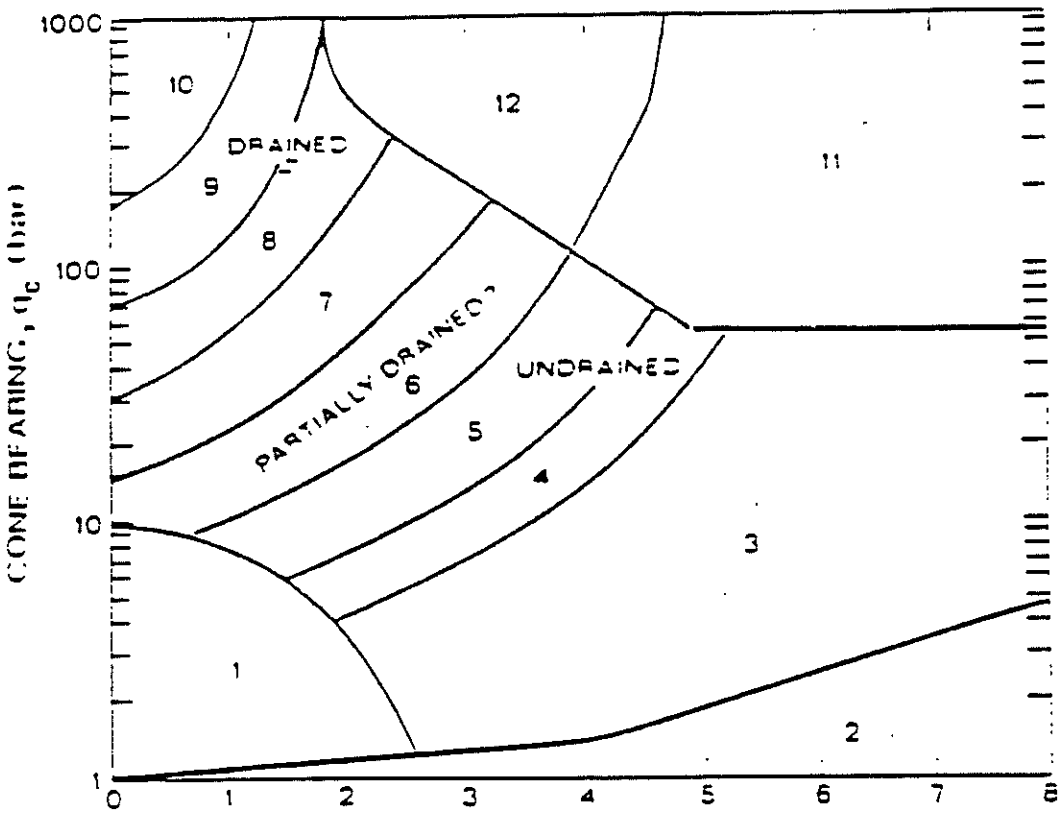
- *Rf-Friction Ratio*: This is the local friction divided by the tip resistance, expressed in percent.

- *Pw-Pore Pressure(U)*: This is the local pore pressure from the formation. U is measured directly behind the cone tip and is measured in kilograms per square centimeter.

- *INC-Inclination*: This is the angle of the cone with respect to the vertical. Inclination has little to do with data interpretation and is generally used as a means of tool protection.

- *Interpreted Soil Type*: This is determined from the tip resistance (Qc) and the friction resistance (Rf) using Robertson & Campenella-1983, based on 60 percent hammer efficiency and 0.15 meter sliding data average.

- *SPT (N)-Standard Penetration Test*: Based on the interpreted soil type and the value of Qc, the SPT (N) value (blows per foot) can be determined. Due to the variance of repeatability and reliability of the SPT test, caution should be used when using the CPT determined N values. These N values should be cross correlated with actual SPT data for comparison.



Zone	q_c/N	Soil Behaviour Type
1)	2	sensitive fine grained
2)	1	organic material
3)	1	clay
4)	1.5	silty clay to clay
5)	2	clayey silt to silty clay
6)	2.5	sandy silt to clayey silt
7)	3	silty sand to sandy silt
8)	4	sand to silty sand
9)	5	sand
10)	6	gravelly sand to sand
11)	1	very stiff fine grained (*)
12)	2	sand to clayey sand (*)

(*) overconsolidated or cemented

1. INTRODUCTION

1.1 SITE DESCRIPTION

The Paducah Gaseous Diffusion Plant (PGDP) is located in western Kentucky approximately 16 kilometers (10 miles) west of Paducah and 6.5 kilometers (4 miles) south of the Ohio River as shown in Fig. 1.1. The PGDP is an operational uranium enrichment facility owned by the U.S. Department of Energy (DOE). Effective July 1, 1993, DOE leased the plant production operations facilities to the United States Enrichment Corporation, which in turn contracted with Lockheed Martin Utility Services, Inc. (LMUS), to provide operations and maintenance services. Bechtel Jacobs Company LLC is responsible for the environmental management activities as the management and integration contractor.

1.2 PURPOSE AND SCOPE OF INVESTIGATION

DOE has focused cleanup efforts to protect human health and the environment by expediting investigative activities whenever possible. As part of this initiative, a geophysical survey was conducted and small trenches (test pits) were excavated at Waste Area Grouping (WAG) 27 to investigate suspected buried objects at Solid Waste Management Unit (SWMU) 1 and additional excavations conducted at SWMU 196 to investigate potentially contaminated sludge from septic tanks. The purpose of this investigation is to combine the remedial investigation (RI) with other ongoing removal actions to streamline contracting and expedite the RI.

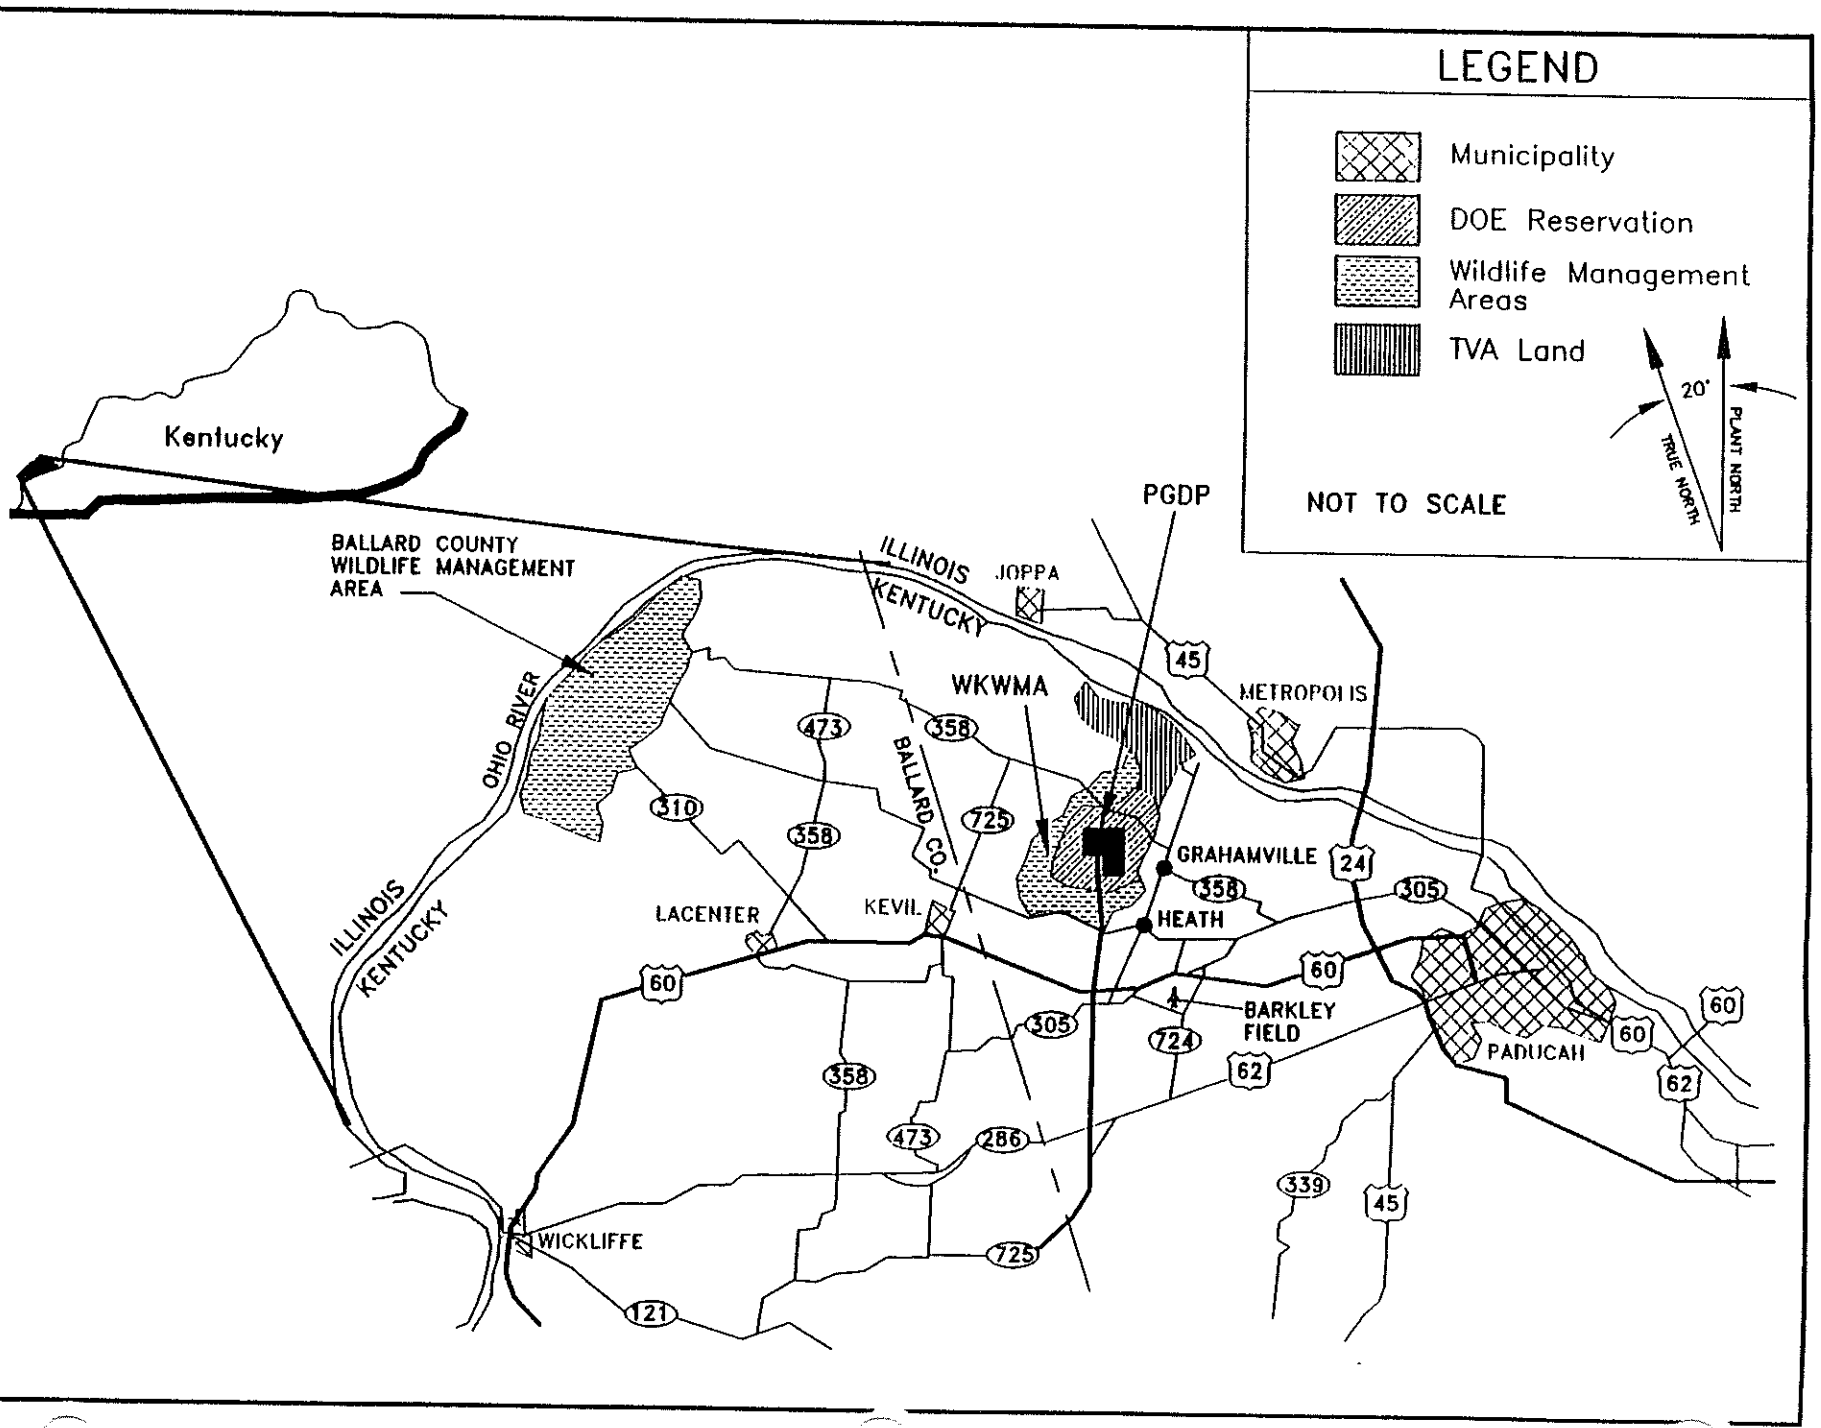
These RI activities at WAG 27 were conducted in accordance with the PGDP Hazardous and Solid Waste Amendments (HSWA) permit and Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). These activities were conducted in conjunction with removal actions at WAG 23 due to the similarity of tasks. WAG 23 activities are described in the Removal Action Report (DOE 1998).

1.3 SITE BACKGROUND

WAG 27 consists of three SWMUs (1, 91, and 196) and the C-720 area. These SWMUs and the C-720 area have been grouped into WAG 27 based on geographical proximity as well as potential commonality of radiological and chemical contamination. SWMU 1, the C-747-C Landfarm is located in the southwest portion of the plant, SWMU 91, the UF_6 Cylinder Drop Test Area is located in the west-central portion, and SWMU 196 in the north-central plant area (Fig. 1.2). The subsurface investigation presented here includes only SWMU 1 and SWMU 196. Data gathered from this investigation augments the ongoing RI for WAG 27. The following site descriptions are derived from the RI/feasibility study work plan (DOE 1996).

1.3.1 SWMU 1—Former Oil Landfarm

SWMU 1, the former oil landfarm, is a potential source of contamination to off-site groundwater, surface water, and sediments. The site is a relatively flat, open, grass covered area that is mowed



A910/7JULY98/1

Fig. 1.1. Paducah Gaseous .usion Plant location map

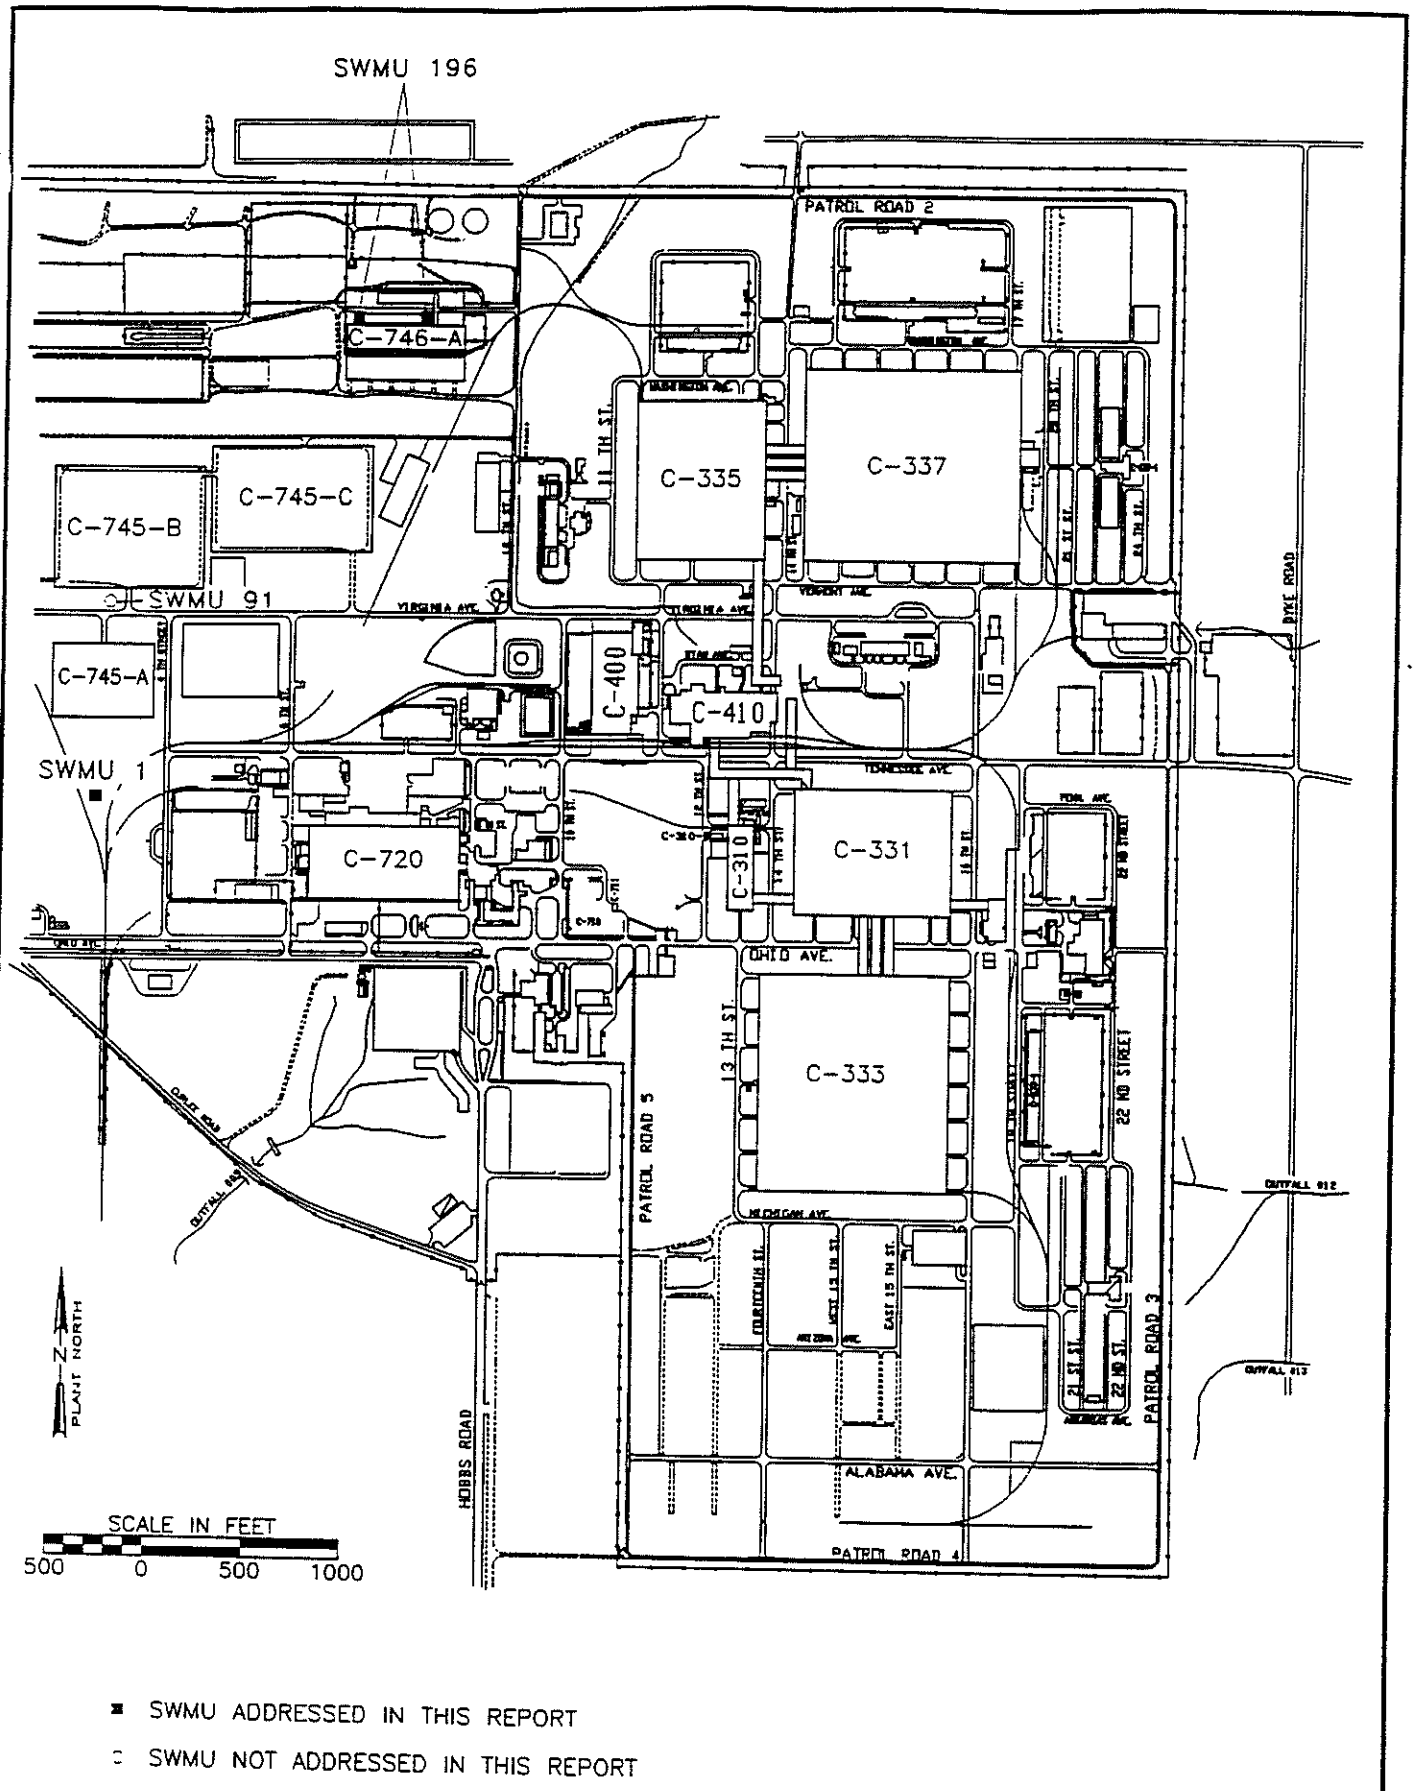


Fig. 1.2. WAG 27 SWMU location map

regularly as part of normal PGDP maintenance operations. The SWMU area is bounded by 4th Street to the east and perimeter ditches on the north, west, and south (see Fig. 1.3). The total area encompassed by SWMU 1 totals 96,300 ft^2. PGDP personnel familiar with disposal practices at the oil landfarm assisted the field team in describing the approximate location, depth, and construction of the former disposal trenches. They described two roughly parallel disposal trenches that were excavated into native soil to an approximate depth of 3–4 ft. A layer of sand and gravel was placed in the bottom of the trenches.

The landfarm was used from 1973 to 1979 for biodegradation of waste oils containing trichloroethene (TCE) 1,1,1-trichloroethane, uranium, and polychlorinated biphenyls (PCBs). It is estimated approximately 5000 gal of waste oils were applied to the landfarm. Previous sampling efforts have identified volatile and semivolatile compounds, radiogenic elements, and metals at SWMU 1.

1.3.2 SWMU 196—Septic Systems at C-746

SWMU 196 is located north of Building C-746-A and consists of two inactive septic systems that served the building. Building C-746-A once housed smelters for discarded aluminum and nickel metals and was used as a warehouse during construction of the main plant. An aluminum smelter was located in the western portion of the building from 1956 until 1985. The nickel smelter was operated in the east end of the building from 1975 until 1985. The building currently is a storage area for hazardous wastes and PCBs.

The septic tanks are located on the northeast and northwest corners (one on each side) of C-746-A and include associated leach fields (Fig. 1.4). The northeast septic system was operated from 1958 until 1980. It processed sanitary waste from a toilet, urinal, bathroom sink, and floor drain. The septic system was modified in 1975 with addition of the nickel smelting operations. Construction of a changehouse and break area added a kitchen sink, water cooler, two showers, a second urinal, and floor drains to the existing system. The septic system was plugged and abandoned in place when Building C-746-A was plumbed into the C-615 sewage treatment plant.

The septic system on the northeast corner of building C-746-A consisted of a 960-gal septic tank and a leach field measuring 60 ft by 20 ft. The leach field consisted of 4-in. drain tiles in shallow soil. The septic system at the northwest corner included a 500-gal septic tank and two vitreous clay pipes that run south and west from the tank.

The northwest septic system operated from 1956 until 1980. The system served a toilet, two showers, a sink, and water cooler. No floor drains were served by this system. The northwest C-746-A septic system was plugged and abandoned in 1980, with the northeast system. A portion of the abandoned system was destroyed during drainage ditch improvements in 1982.

1.3.3 SWMU 91—Cylinder Drop Test Area

SWMU 91, the UF_6 Cylinder Drop Test Area, was not included with this excavation program and will be investigated with the ongoing WAG 27 RI.

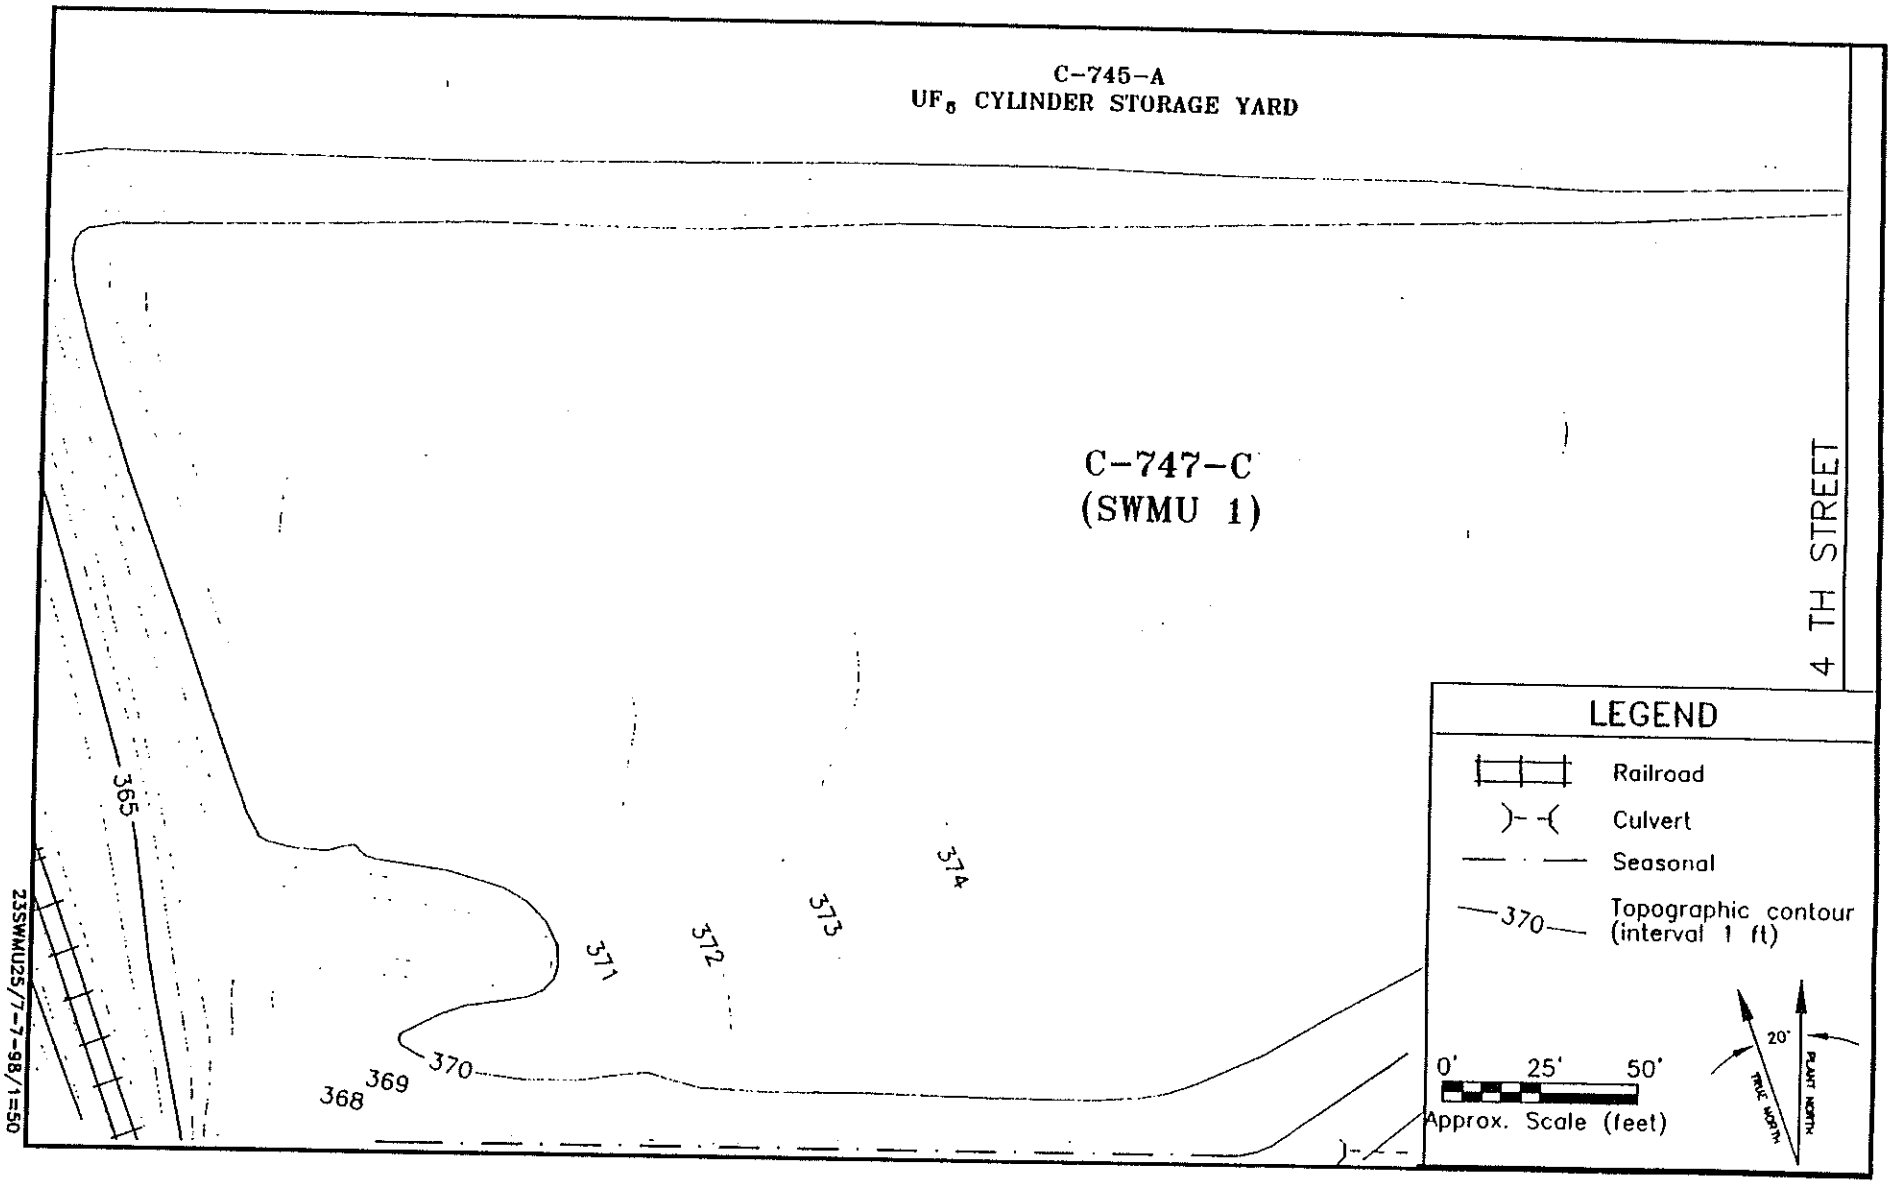

Fig. 1.3. Site location map for the C-747-C Oil Landfarm (SWMU 1)

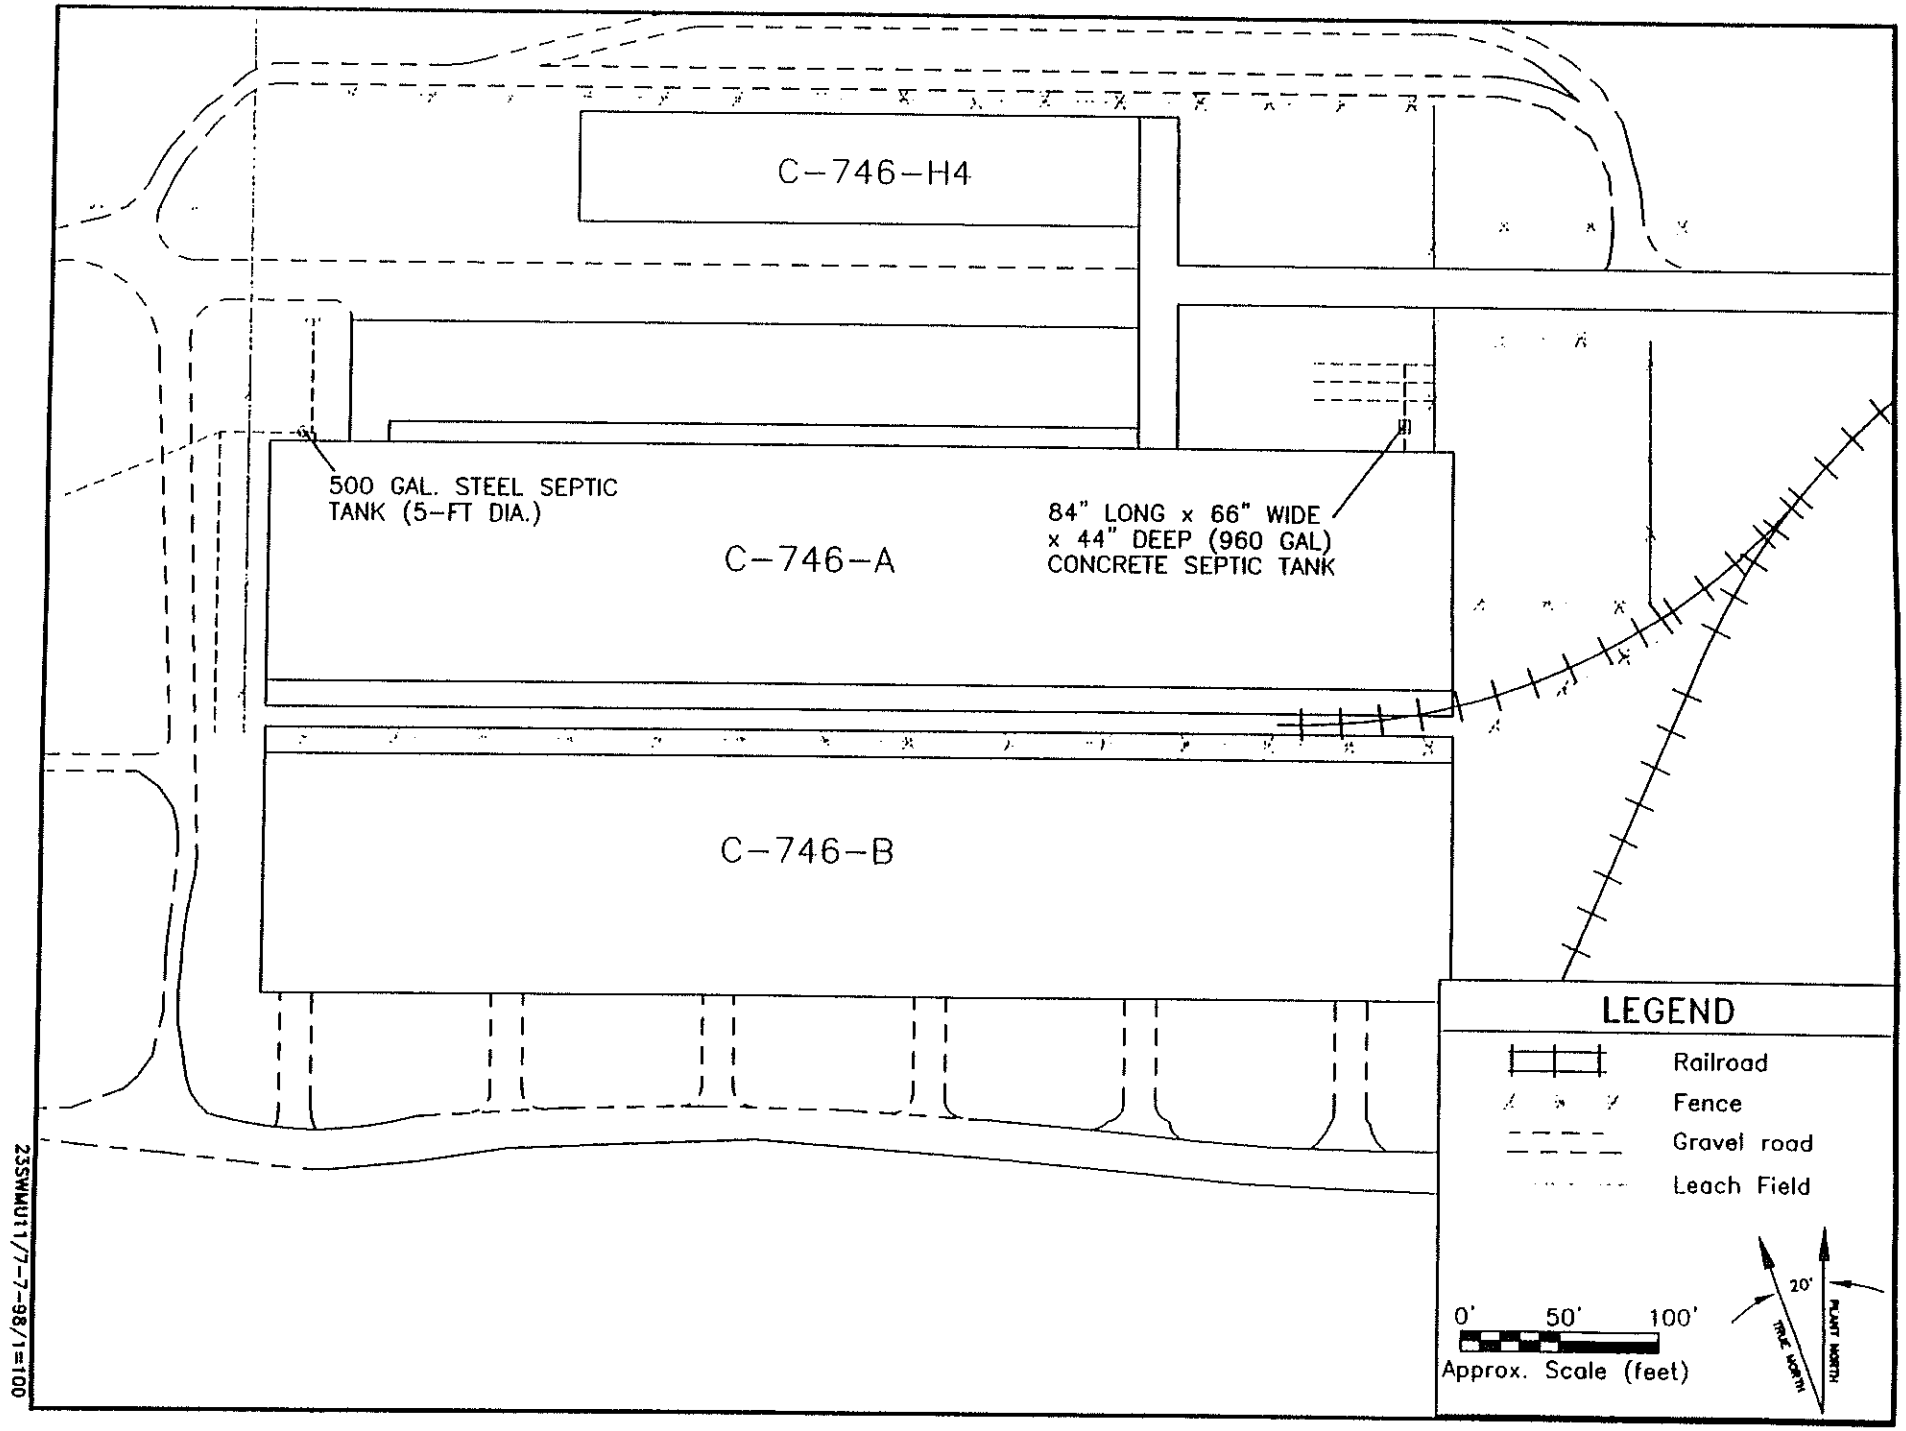

Fig. 1.4. Site location map for C-746-A septic tanks (SWMU 196)

1.4 PROJECT PLANNING

All field activity was conducted in accordance with the WAG 23 and WAG 27 Sampling, Quality Assurance, and Data Management Plan (LMES 1997). This document served as the project work plan, providing details of:

- project organization, responsibilities, and training;
- details of sampling and analysis procedures;
- data collection, review, validation, and usage;
- quality assurance/quality control;
- document control and records management; and
- waste management.

1.5 FIELD IMPLEMENTATION

RI activity was initiated at SWMU 1. Field activities began on January 20 and were completed on January 30, 1998. The geophysical survey was completed first to provide detailed locations of the magnetic anomalies to guide excavation of the test pits that followed. Section 2.2 discusses technical aspects of the geophysical survey. Excavation of the test pits at SWMU 1 is discussed in Sect. 3.2.

Excavation of the septic tanks at C-746-A was begun on February 2 and completed on February 6, 1998. The field effort entailed location and excavation of the tanks, removal and storage of the sludge, sampling and backfilling the excavation, and site reclamation. These activities are described in Sect. 4. All field activities were documented in the field logbook according to Paducah procedure PMSA-1201, "Logbooks".

1.5.1 Mobilization/Demobilization

Mobilization activities were initiated on December 2 and completed on December 19, 1997. Mobilization included:

- procurement of equipment, materials, and resources to conduct field activities;
- site-specific training;
- establishment and organization of project files;
- submittal and approval of key personnel;
- preparation and approval of the project-specific security plan; and
- initiation of excavation permit.

A Lockheed Martin Energy Systems, Inc. (LMES) operational readiness review was completed on December 10, 1997, at the LMES Environmental Management and Enrichment Facilities (EMEF) Office in Kevil, Kentucky. Conditional approval to begin field activities was granted at this meeting, subject to receipt of proper excavation permits. A field planning meeting was held on December 19, 1997, to discuss project requirements with site personnel and subcontractors.

A field support facility was established at the C-755 Support Facility, located on the east side of PGDP adjacent to Gate 48. This location was chosen because it provided more efficient access than was originally anticipated. Trailer C-755-T-1-3 was subleased from DKM Construction for the duration of the project.

1.5.2 Waste Management

All soil removed during excavation of the test pits and septic tanks was returned to the excavation following sampling, thus minimizing waste generation. LMUS Chemical Operations personnel removed the contents of the septic tank using a Keith-Hubner King-Vac vacuum pump truck. Sludge removed from the septic tanks was mixed with granular absorbent and placed in 55-gal drums. The absorbent was added to remove any excess liquid contained in the sludge. All drums were labeled according to Paducah EMEF procedure PMWM-1002 "On-Site Handling and Disposal of Waste Materials." Information recorded directly on the drums included the request for disposal number, contents, generation date, location, and weight of the filled container.

Other investigative derived wastes generated during this field exercise include disposable personal protective equipment (PPE), hypalon sheeting, and water collected from equipment decontamination. Table 1.1 summarizes the types and quantities of investigative derived wastes from this field effort.

Table 1.1. Summary of wastes generated during the SWMU 1 test pits and SWMU 196 septic tank closures

Quantity	Contents	Reference number
1 55-gal drum	Hypalon sheeting	RFD #58515
1 55-gal drum	PPE	RFD #58516
5 gal	Decontamination liquids	RFD #58517[a]
11 55-gal drums	Septic tank sludge (northeast tank)	RFD #58514
10 55-gal drums	Septic tank sludge (northwest tank)	RFD #58513

[a] All fluids contained in sample vessels for analysis—no fluid remained after sampling.

1.5.3 Decontamination Procedures

Test pits at SWMU 1 and septic tanks sampled at Building C-746-A were excavated with either a Nissan N21SS Mini-Giant excavator or a Case 580L backhoe. The excavator and backhoe buckets and miscellaneous hand tools were decontaminated between the two sites using EMEF procedure PTSA-5002, "Decontamination of Field Equipment." Decontamination was conducted using a portable basin to collect excess fluids. The fluids were sampled at the conclusion of the project.

Sampling equipment was decontaminated between samples using EMEF procedure PTSA-5002, "Decontamination of Field Equipment" and PTSA-5005, "Decontamination of Sampling Containers and Sampling Devices." The effectiveness of decontamination was verified by collecting equipment rinseate samples. Field sampling equipment used for this investigation consisted of stainless steel trowels, spoons, and bowls.

1.5.4 Health and Safety

The TN & Associates/CDM Federal Programs Corporation (TN&A/CDM Federal) Site Health and Safety Officer (SHSO) performed onsite monitoring for VOCs during all removal action activities using a MultiRae® photoionization detector (PID) and Geiger-Muller (GM) device to monitor for radioactivity. No elevated readings were recorded that required any modification of PPE. Daily tailgate safety meetings were conducted at the field office before the start of any field activity. These meetings were conducted by the SHSO to discuss health and safety issues and any special concerns

associated with the site. All activities were conducted in Level D PPE consisting of coveralls. hard hats, steel-toed boots, and safety glasses.

1.5.5 Audits/Surveillances

The TN&A/CDM Federal QA Coordinator conducted a field surveillance on February 3, 1998. The surveillance focused on sampling and decontamination procedures used during the C-746 field activities. There were no findings or nonconformances from the surveillance.

2. WAG 27 GEOPHYSICAL SURVEY AT SWMU 1

The geophysical survey at SWMU 1 within WAG 27 was conducted as part of the WAG 27 RI. The survey was performed by TN&A/CDM Federal personnel on January 20, 1998. The equipment used to conduct the survey was the Geonics™ EM-61 high sensitivity metal detector. The EM-61 electro-magnetometer is used to detect both ferrous and nonferrous metallic objects and is capable of detecting a single 55-gal drum at a depth of over 9 ft below ground surface (bgs) beneath the instrument, yet it is relatively insensitive to interference from nearby surface metal such as fences, buildings, cars, etc. In addition, the instrument is practically independent of the electrical conductivity of the subsurface material.

2.1 PURPOSE OF GEOPHYSICAL SURVEY

Previous geophysical investigations identified two small magnetic anomalies at SWMU 1 (CH2M HILL 1992). However, the original survey covered a large area with relatively few measurement points. The purpose of this geophysical survey was to better delineate the boundaries of the anomalies in two general areas within the former land farming area. Based on the data generated during the survey, the boundaries of anomalous areas were identified using red pinflags. A civil survey was performed to provide PGDP coordinates of the anomalies and primary grid stake locations. A copy of the survey data is included as Appendix A. After the coordinates were established, test pits were performed to confirm the depth and type of materials buried at SWMU 1.

2.2 GEOPHYSICAL SURVEY AT SWMU 1

Geophysical surveys were conducted at three areas at SWMU 1: (1) a background survey, (2) Grid A in the vicinity of a previously defined magnetic anomaly, and (3) Grid B in the vicinity of a second anomaly. The following sections discuss each of these surveys.

2.2.1 Background Survey

A background survey was performed in an area having no history of site activity, receiving no drainage from potentially impacted areas of the site, and representing natural soil conditions. The first area selected for the background survey was located immediately south of the areas to be surveyed; however, this location was determined to be unacceptable because of underground utilities discovered during a site walkover. An alternate location was selected immediately north of Grids A and B; the location of each survey area is shown on Fig. 2.1. The dimensions of the background survey area were 50 by 20 ft, resulting in 18 measurements (at 10-ft intervals). Measurements recorded at each grid node are presented in Fig. 2.2 and provided in Appendix B.

A base station was selected in the background area at the 20N + 20E location (see Fig. 2.2). Three base station measurements were recorded. The purpose of the base station measurements (one measurement three times per day) was to evaluate changes in instrument response and natural changes in the earth's magnetic field. Base station measurements are provided on Fig. 2.2 and in Appendix B.

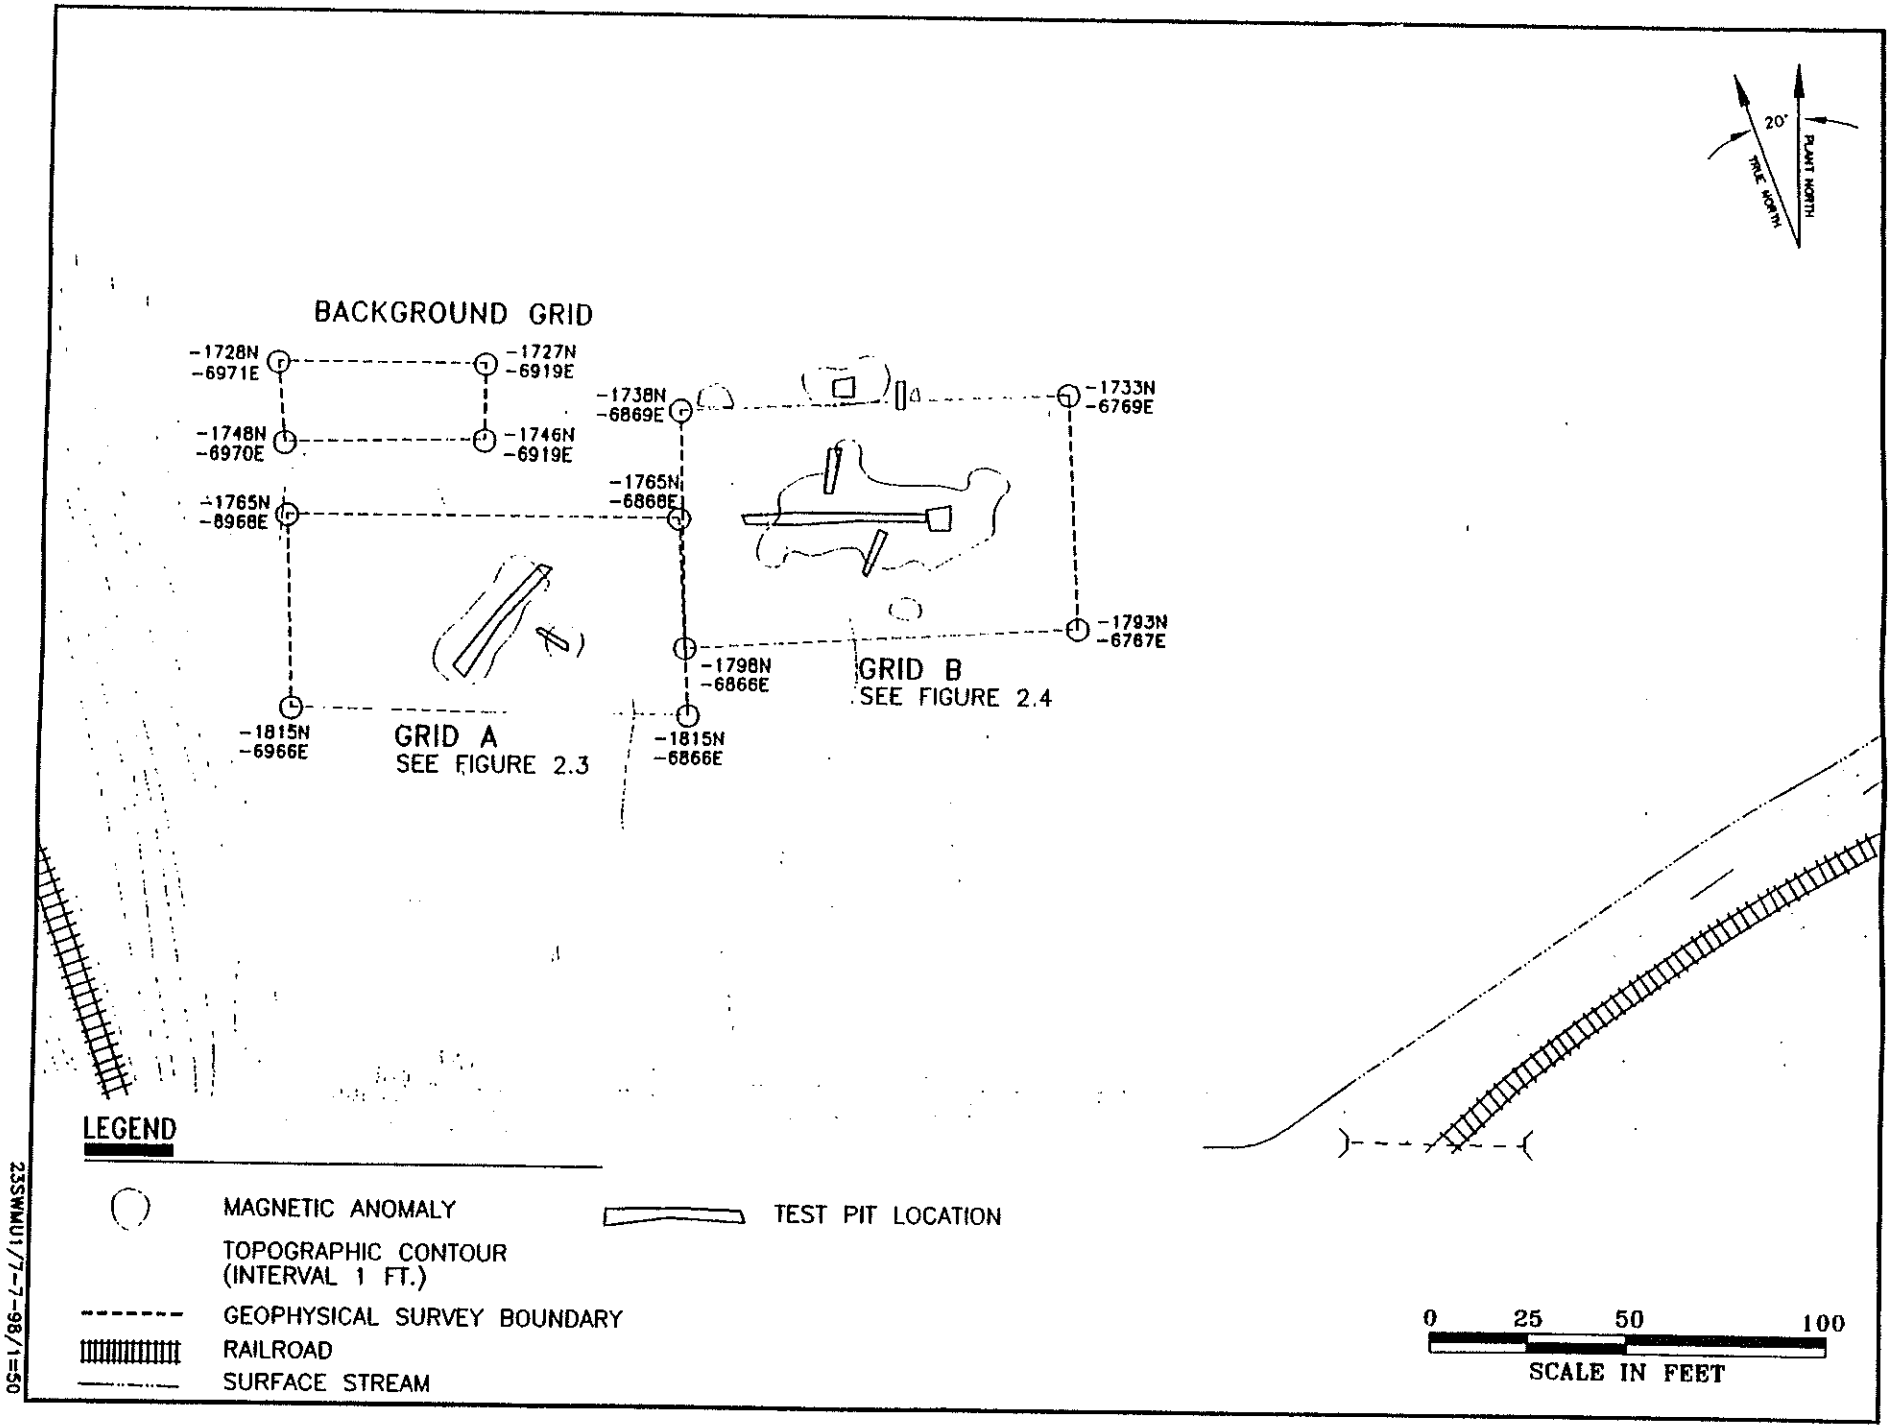

Fig. 2.1. Survey grids and identified anomalies at SWMU-1

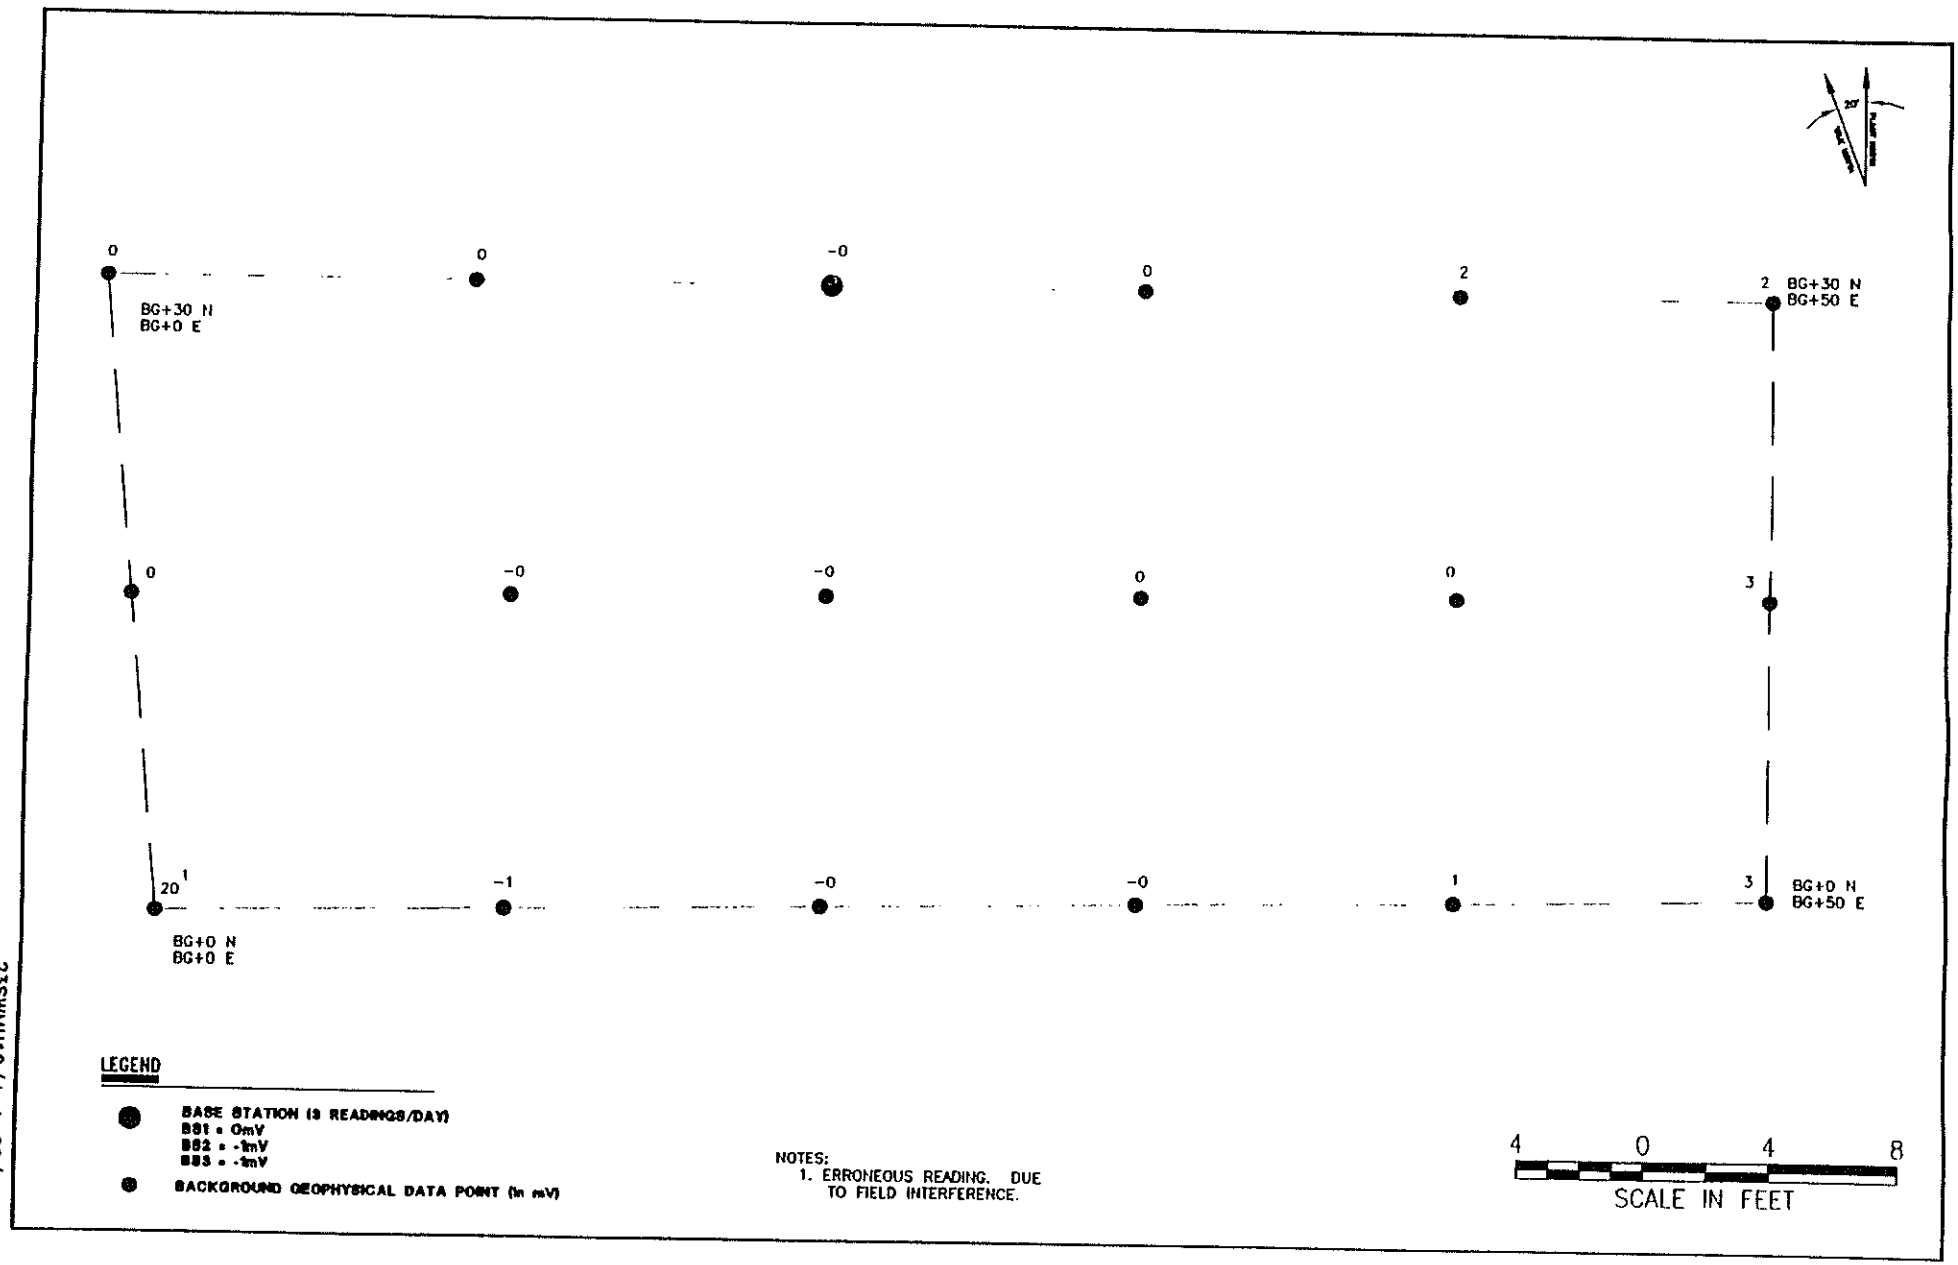

23SWMU12/4-1-98/1=4

Fig. 2.2. Background Grid Geophysical Survey Measurements

Background measurements ranged from -1 to 3 mV on Channel 1 (the top coil); one measurement of 20 mV was disregarded because of field interferences (e.g., a metal clipboard). For the purpose of identifying anomalies, background was considered to be 3 mV or less.

Base station measurements were 0 mV, -1 mV, and -1 mV measured at the beginning of the survey, at noon, and at the conclusion of the survey, respectively. It was concluded that changes in site conditions and instrument response throughout the day were negligible.

2.2.2 Grid A Survey

The geophysical survey of Grid A was performed across a 100 ft ×50 ft area. One person operated the EM-61 and one person transcribed data and other pertinent information in the geophysical logbook. Measurements were recorded only at grid nodes; however, the EM-61 is equipped with an audible mechanism that increases in intensity and volume as measurements increase. Therefore, as the survey was conducted, red pinflags were placed at all locations (on and between grid nodes) where the instrument indicated an increase in the magnetic field. Once a measurement was recorded at each grid node, the surveyor further refined the boundaries of anomalous areas and recorded maximum measurements within the anomalous areas. The dimensions and locations of each anomaly were documented in the geophysical logbook.

Two anomalous areas were identified within Grid A. These anomalies and measurements recorded at each grid node are shown on Fig. 2.3. The anomalies are located in the approximate center of the grid. That suggests the grid was properly placed where the earlier survey had identified metallic objects. A much smaller anomaly at the northeast corner is possibly part of the same anomaly. The contours surrounding the anomalies are approximately 10 mV contours. Maximum measurements were made within the boundaries to approximate the depth to the top of buried materials. Based on instrument measurements within the anomalies, they appear to be mounded with depths ranging from 2.25 to 4.8 ft bgs along the crest of the mound. Perimeter depths are estimated to be approximately 7.0 ft bgs.

2.2.3 Grid B Survey

The geophysical survey of Grid B was performed across an area 100 ft × 60 ft. This area was surveyed in the same manner as Grid A. Five anomalous areas were identified and are shown on Fig. 2.4.

Anomalies identified within Grid B consist of one large anomaly and four smaller anomalies. Again, perimeter contours represent approximately 10 mV and a depth of approximately 7.0 ft bgs. Maximum measurements within the largest anomaly ranged from 340 mV to 4000 mV for different portions of the anomaly. This anomaly also indicated a mounded shape with the crest lying approximately 0.45–2.4 ft bgs. The locations of the smaller anomalies are also shown on Fig. 2.4.

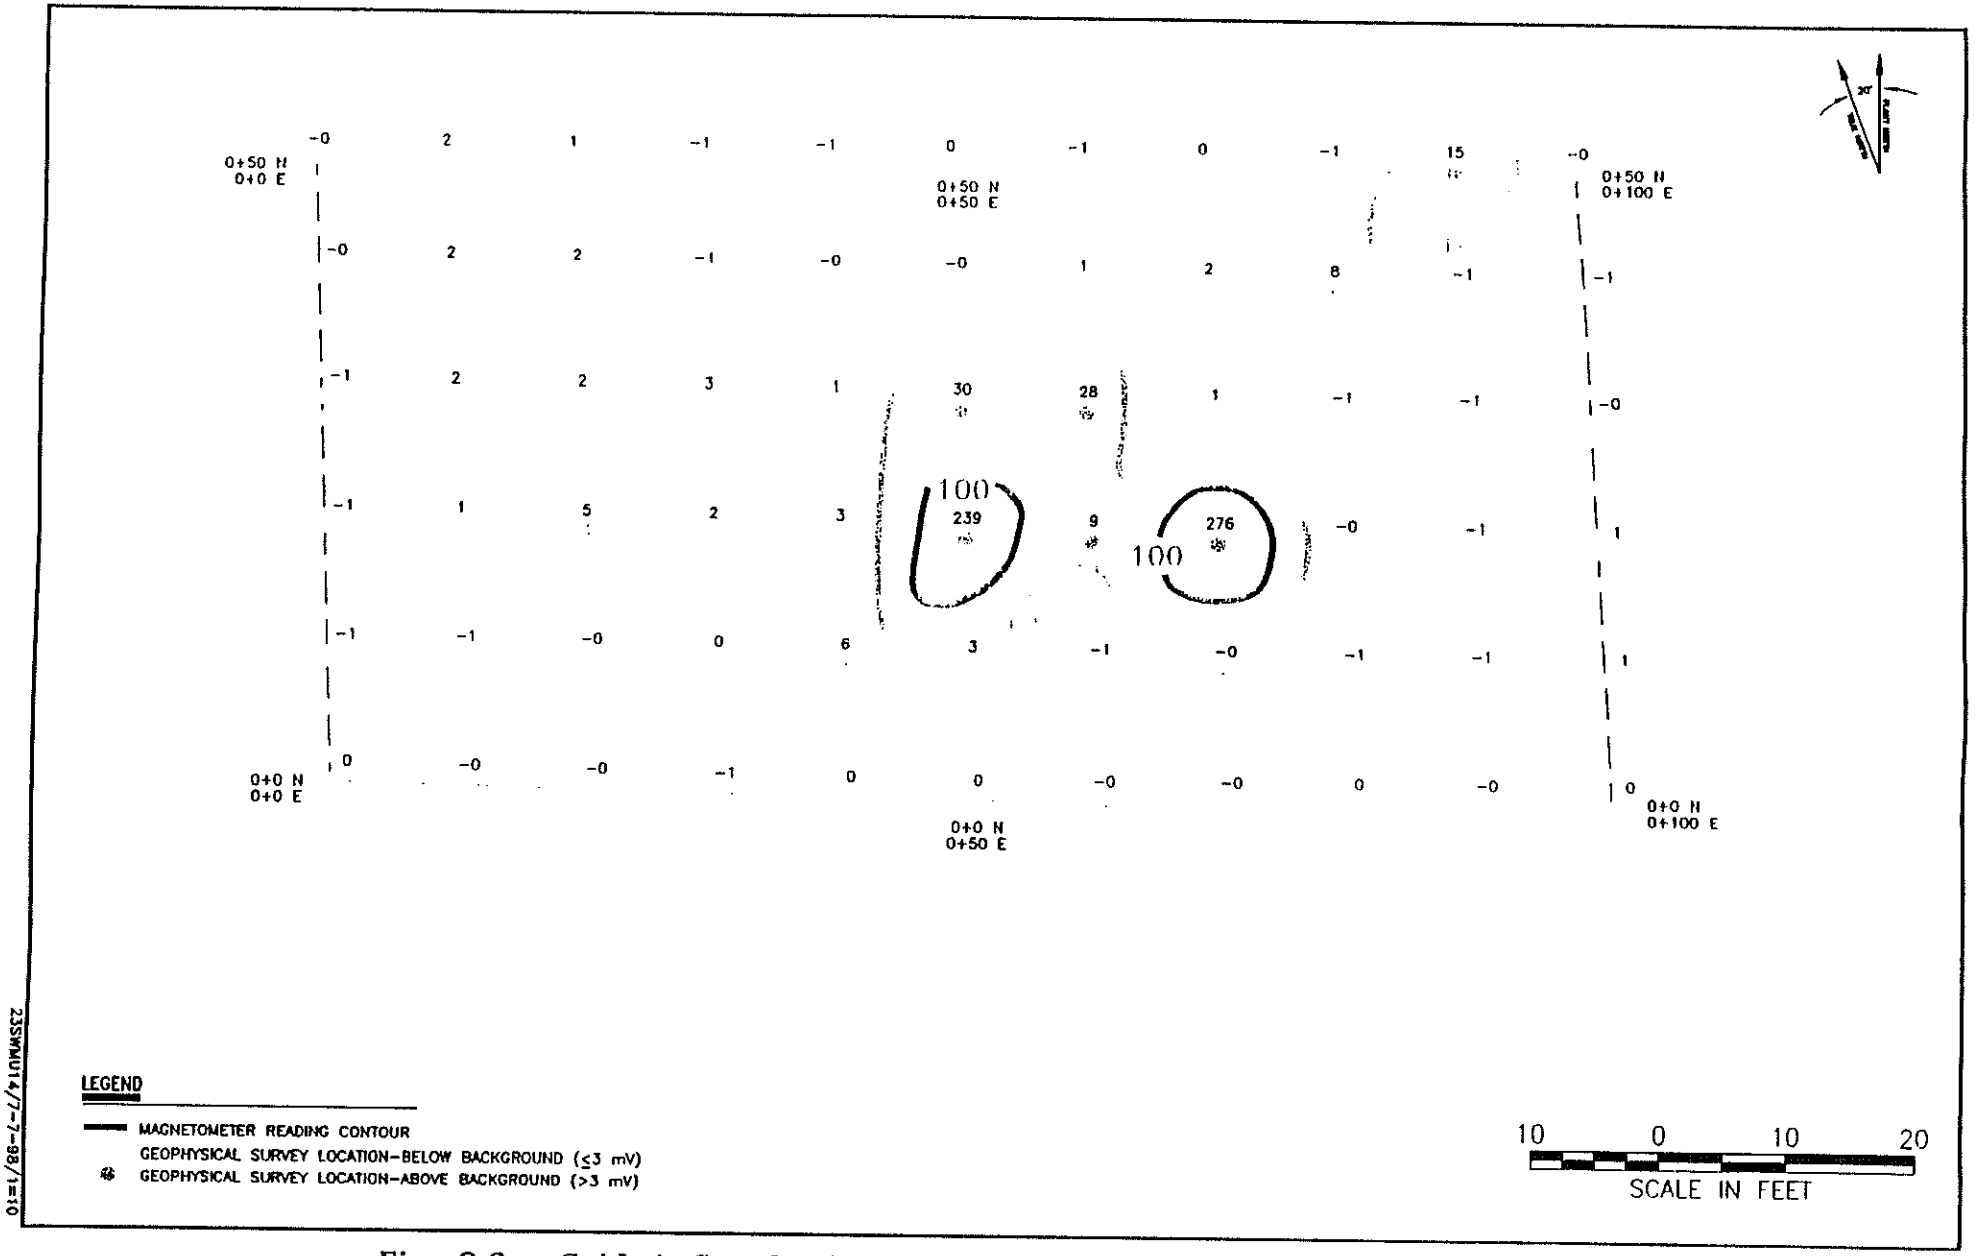

Fig. 2.3. Grid A Geophysical Survey Measurements and Contour Map

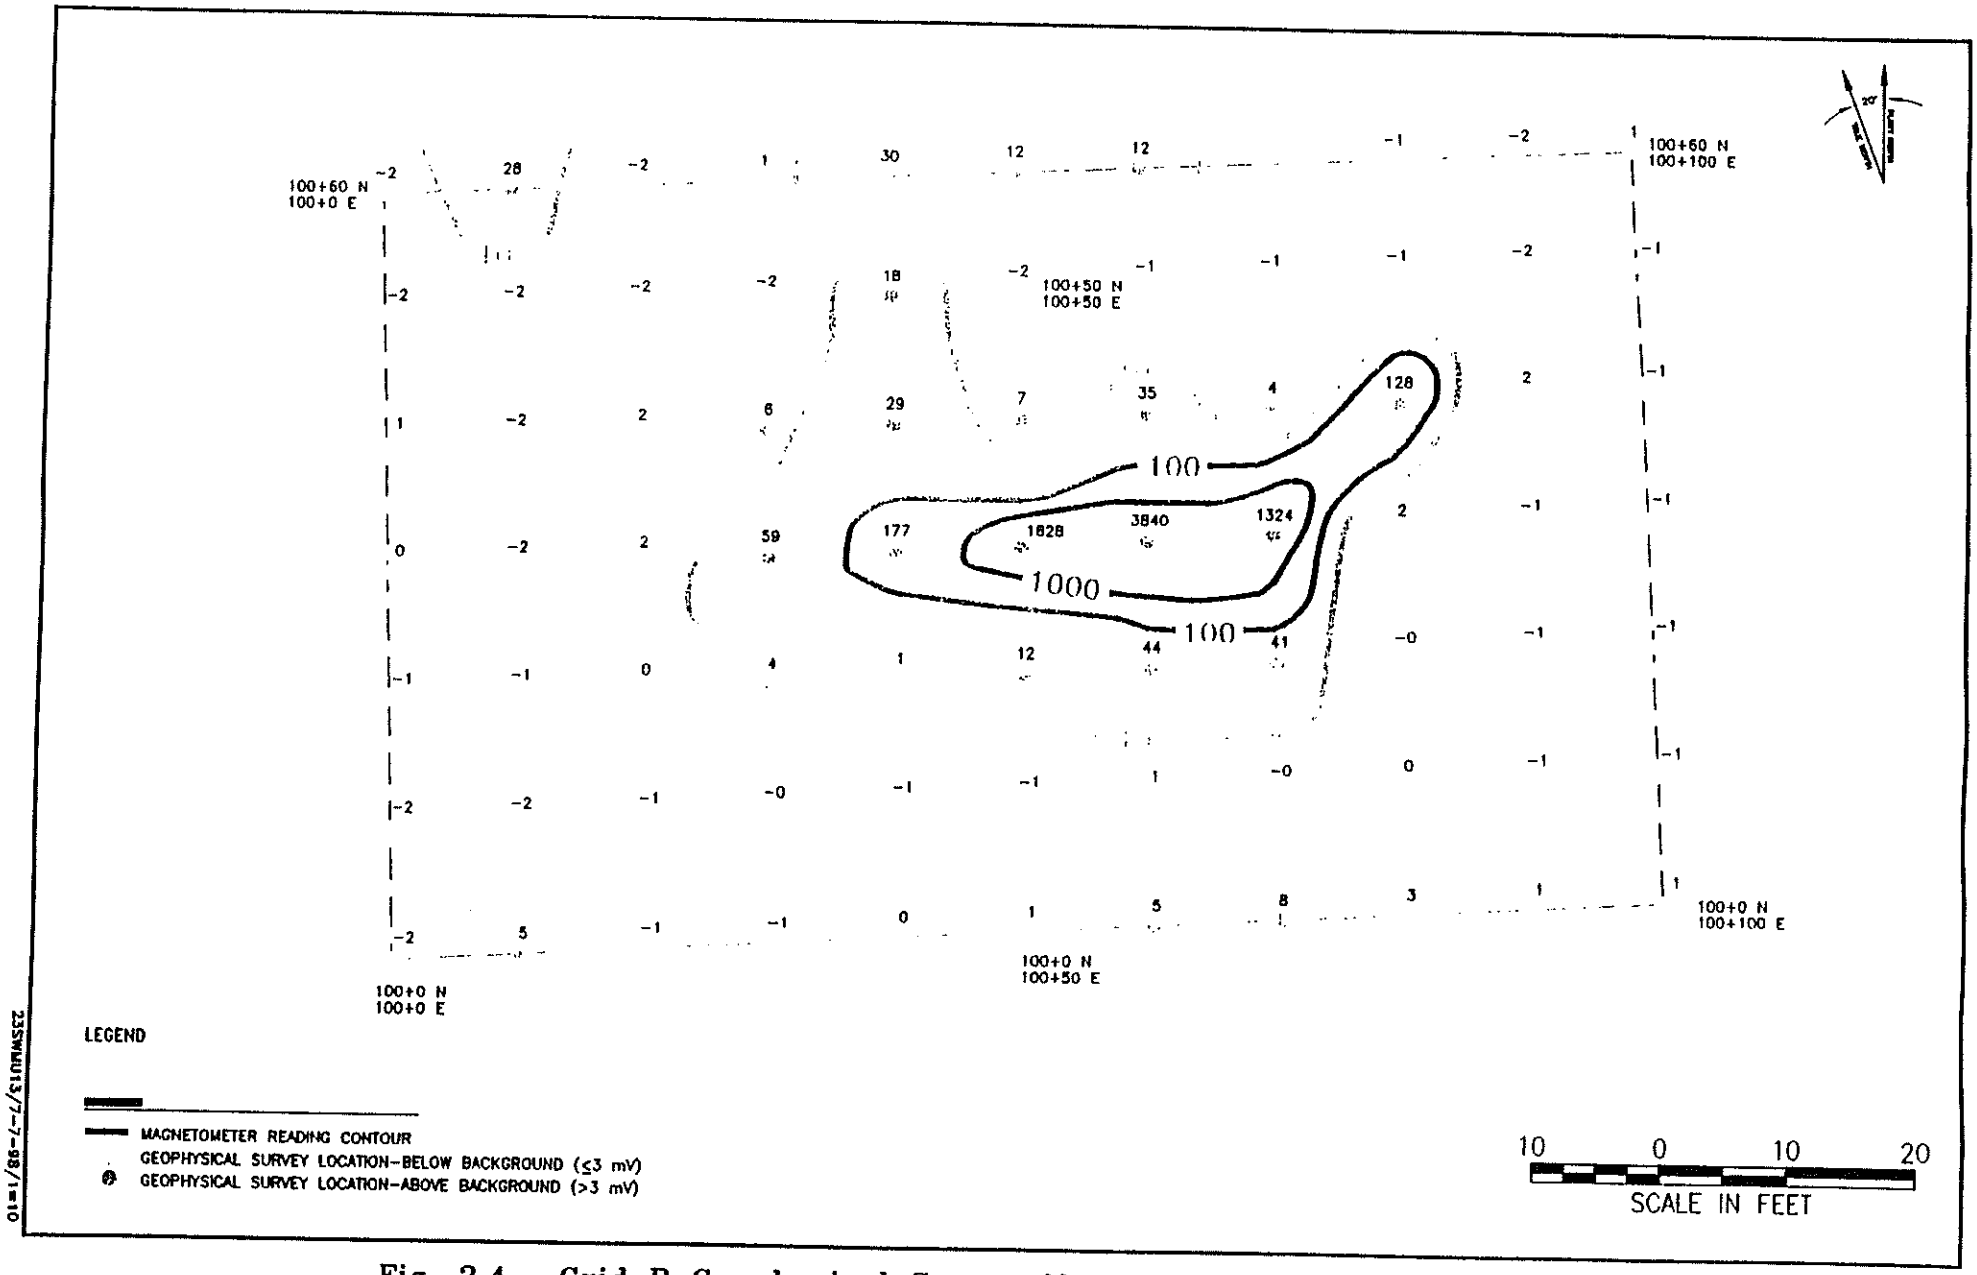

Fig. 2.4. Grid B Geophysical Survey Measurements and Contour Map

3. EXCAVATIONS AT SWMU 1

Test pits were excavated at SWMU 1 to investigate the source magnetic anomalies discerned from the geophysical survey. This section presents the results of the subsurface investigation.

3.1 PURPOSE OF TEST PITS AT SWMU 1

Test pits were required at SWMU 1 because the method allows removal of overburden and larger objects. Test pits are preferred in this type of application because they are less limited by subsurface obstructions and allow for completely uncovering buried objects so they can be identified. The purpose of the test pit program was to determine the nature of the metallic objects identified in the geophysical survey and determine if those objects have contributed to contamination at the SWMU.

3.2 TEST PIT PROGRAM AT SWMU 1

Interpretation of the magnetometer survey data identified and located the limits of seven anomalies within SWMU 1. In general, the magnetic anomalies approximated the location of two roughly parallel disposal trenches in (and immediately north of) Grid B, and a smaller area in Grid A. Test pits were positioned by field personnel to best characterize the geophysical anomalies. Test pits were excavated using a Nissan Mini-Giant® Excavator and a Case 580L backhoe.

The pits were not excavated in any particular order, but Grid B was investigated first followed by Grid A. Within each grid, the test pits were not sequenced by pit number (i.e., TB-5 was excavated first followed by TB-2, TB-4, TB-1, TB-3, and TB-6), following a strategy to first characterize the center of the anomaly, then determine the extent of material along the margins. The pits were often expanded to further investigate features observed by the field team. Soil samples were collected from select locations according to Paducah EMEF procedure PTSA-4201, "Surface Soil Sampling." Analytical requirements for the test pits included VOCs, SVOCs, PCBs, metals, and a selected suite suite of radiological analyses (^{60}Co, ^{235}U, ^{99}Tc, ^{239}Pu, ^{241}Am, ^{237}Np, ^{230}Th, ^{137}Cs, and total uranium). Table 3.1 summarizes the rationale employed for test pit locations and results of the investigation. Figure 3.1 illustrates the location of test pits in Grid B and Fig. 3.2 illustrates test pit locations in Grid A. Table 3.2 provides a summary of analytical samples collected in association with the SWMU 1 test pits.

3.3 GRID B INVESTIGATION

Test pit TB-5 was excavated first to investigate the northernmost magnetic anomaly. The pit was located in the approximate center of the anomaly within an area of a suspected trench at the former landfarm. The excavation was advanced to a depth of 3.5 ft where an interval of blue-grey silt was uncovered. The silty layer exhibited an oily appearance and had a noticeable odor. Field instrumentation detected organic vapors over 100 ppm and recorded elevated readings on the radiologic meter [1000 counts per minute (cpm)]. The pit was backfilled and marked as a radiological area by PGDP health physics personnel. The final dimensions of the test pit measured 2 ft by 2 ft by 3.5 ft (length by width by depth). No metallic objects were uncovered, only a plastic drum lid.

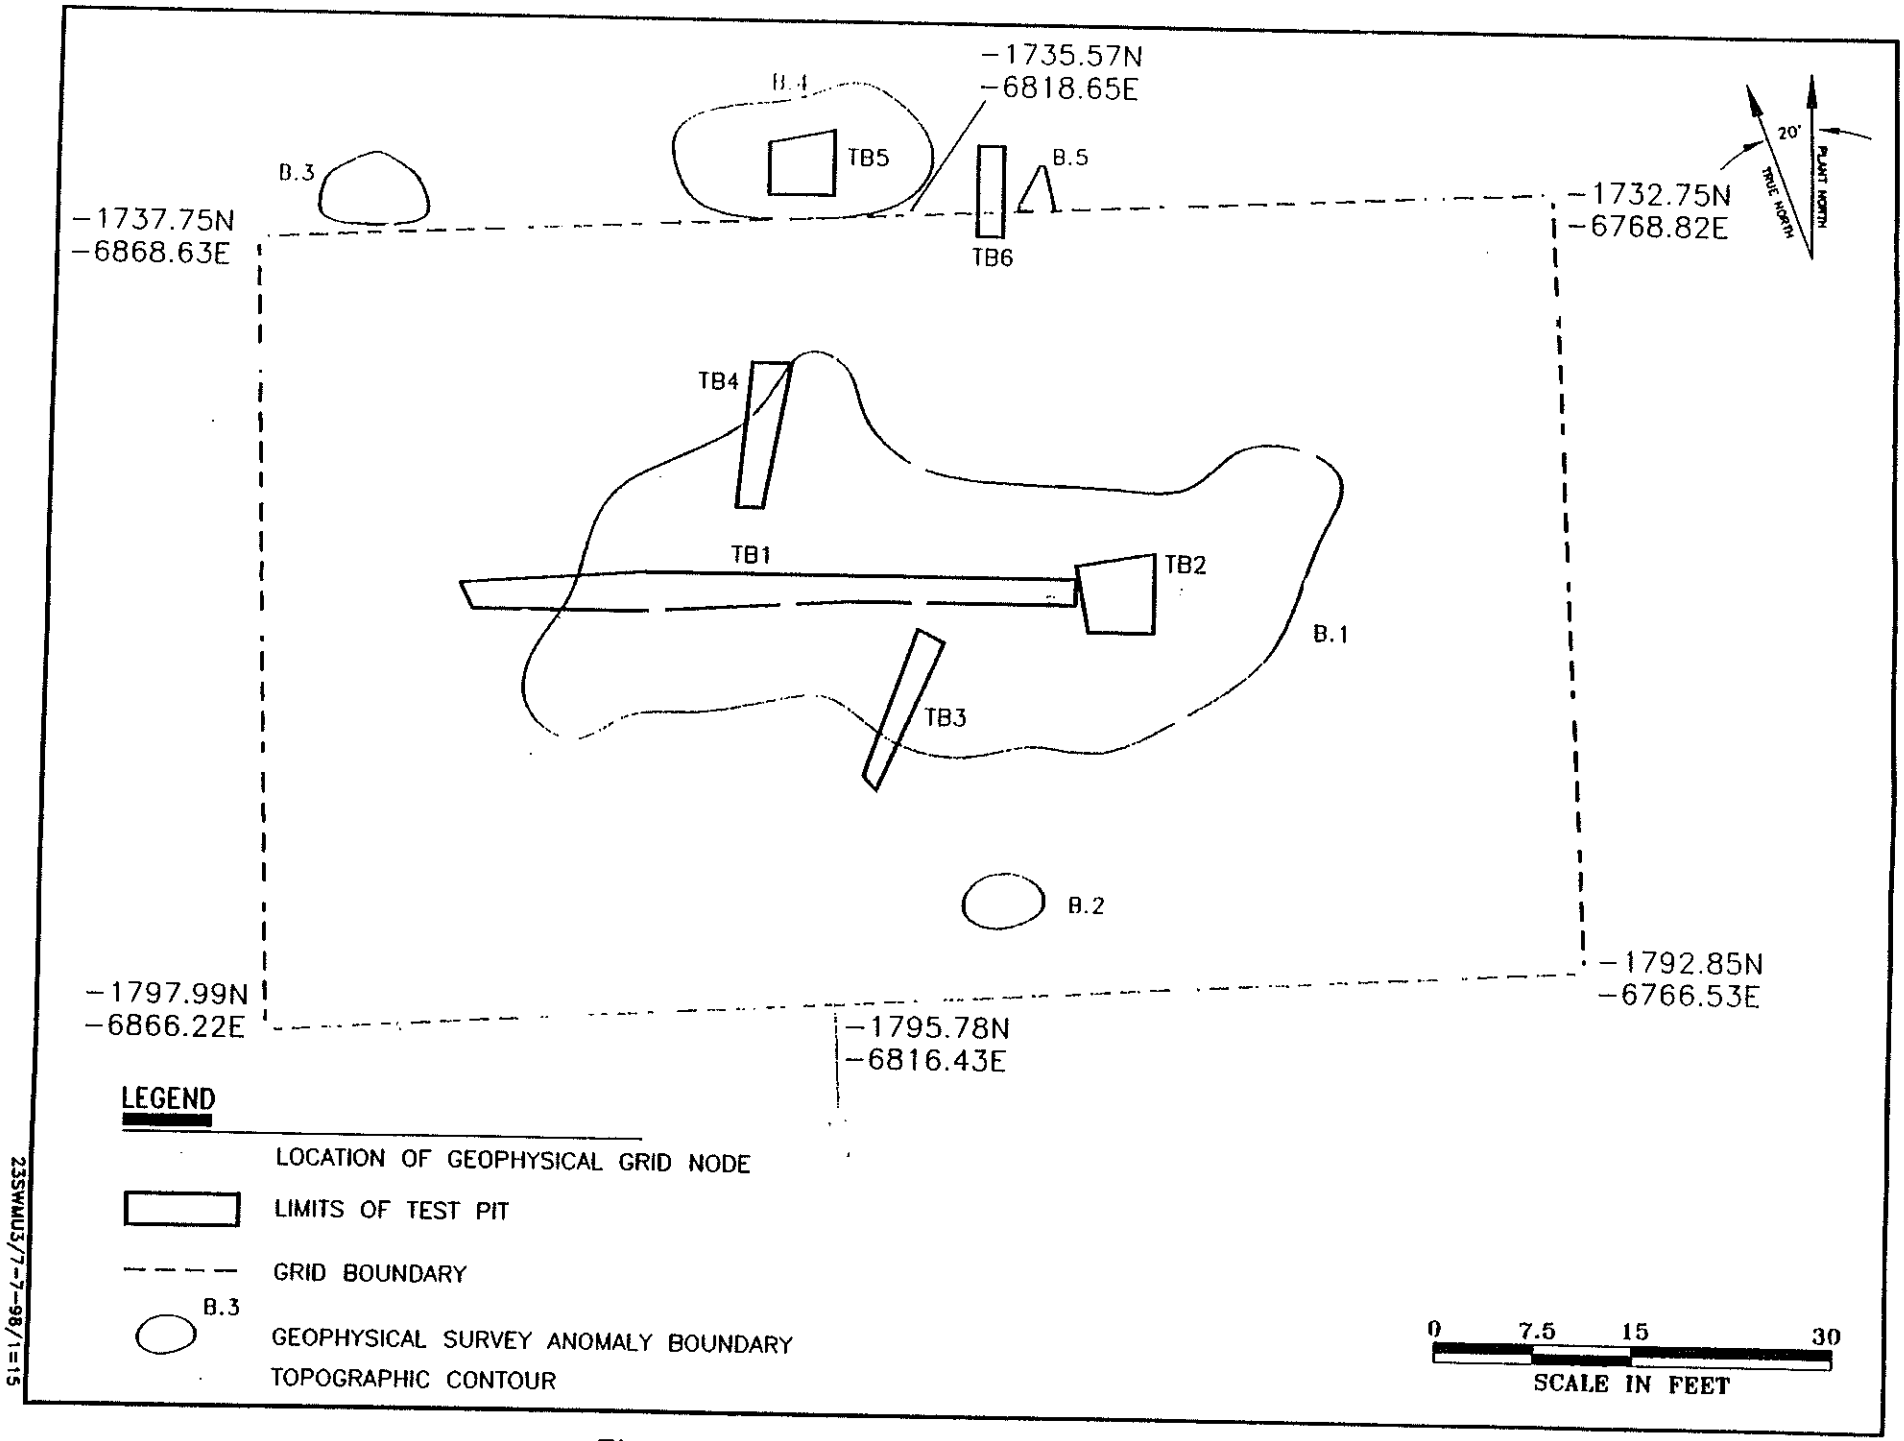

Fig. 3.1. Location of test pits at Grid B

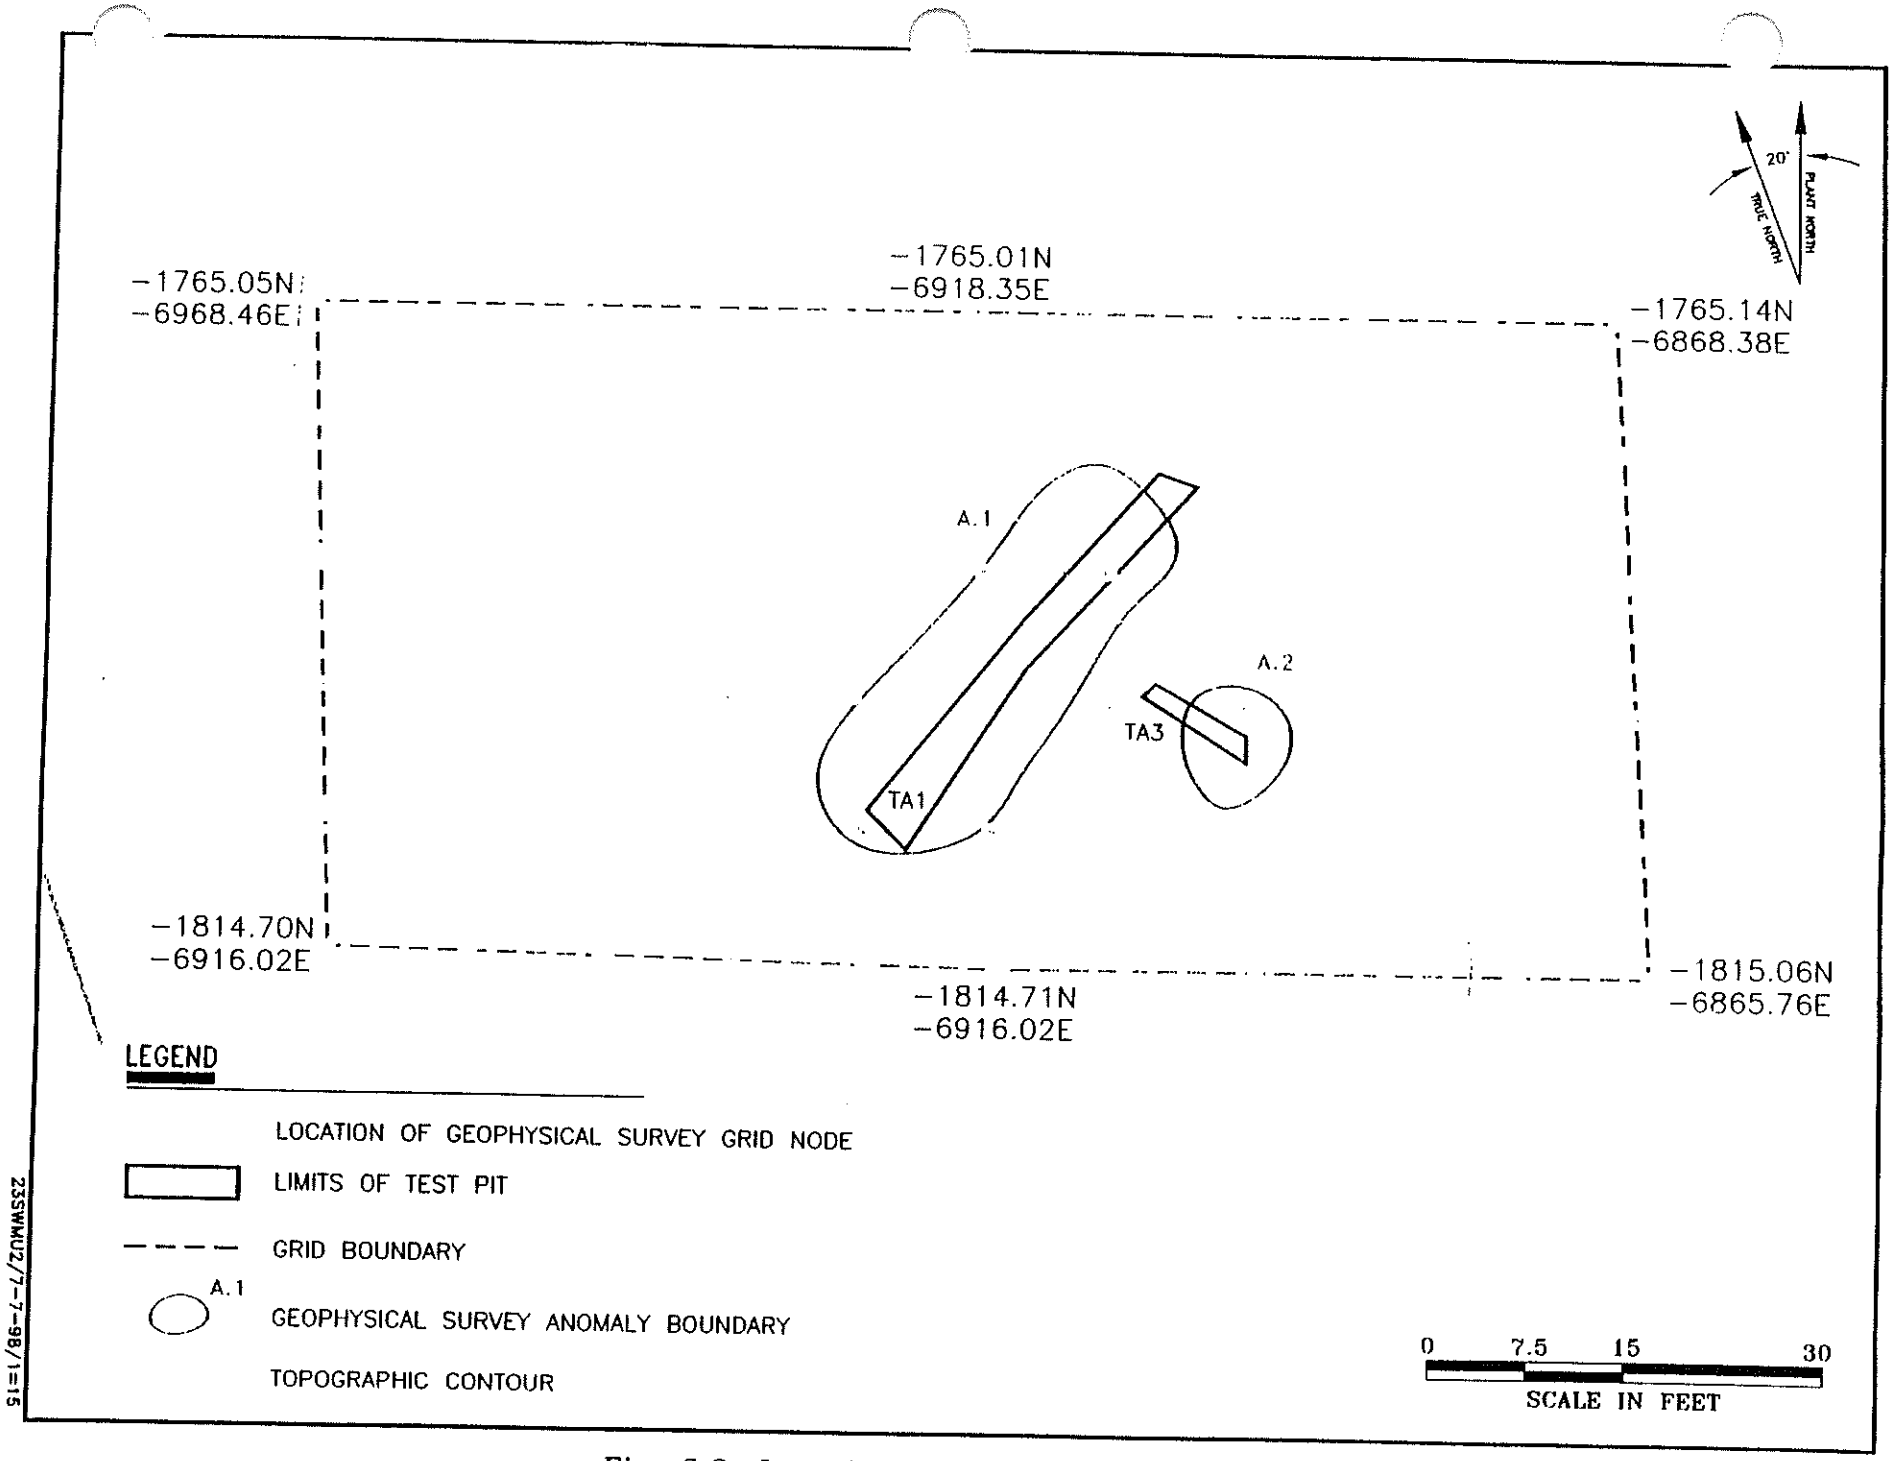

Fig. 3.2. Location of test pits at Grid A

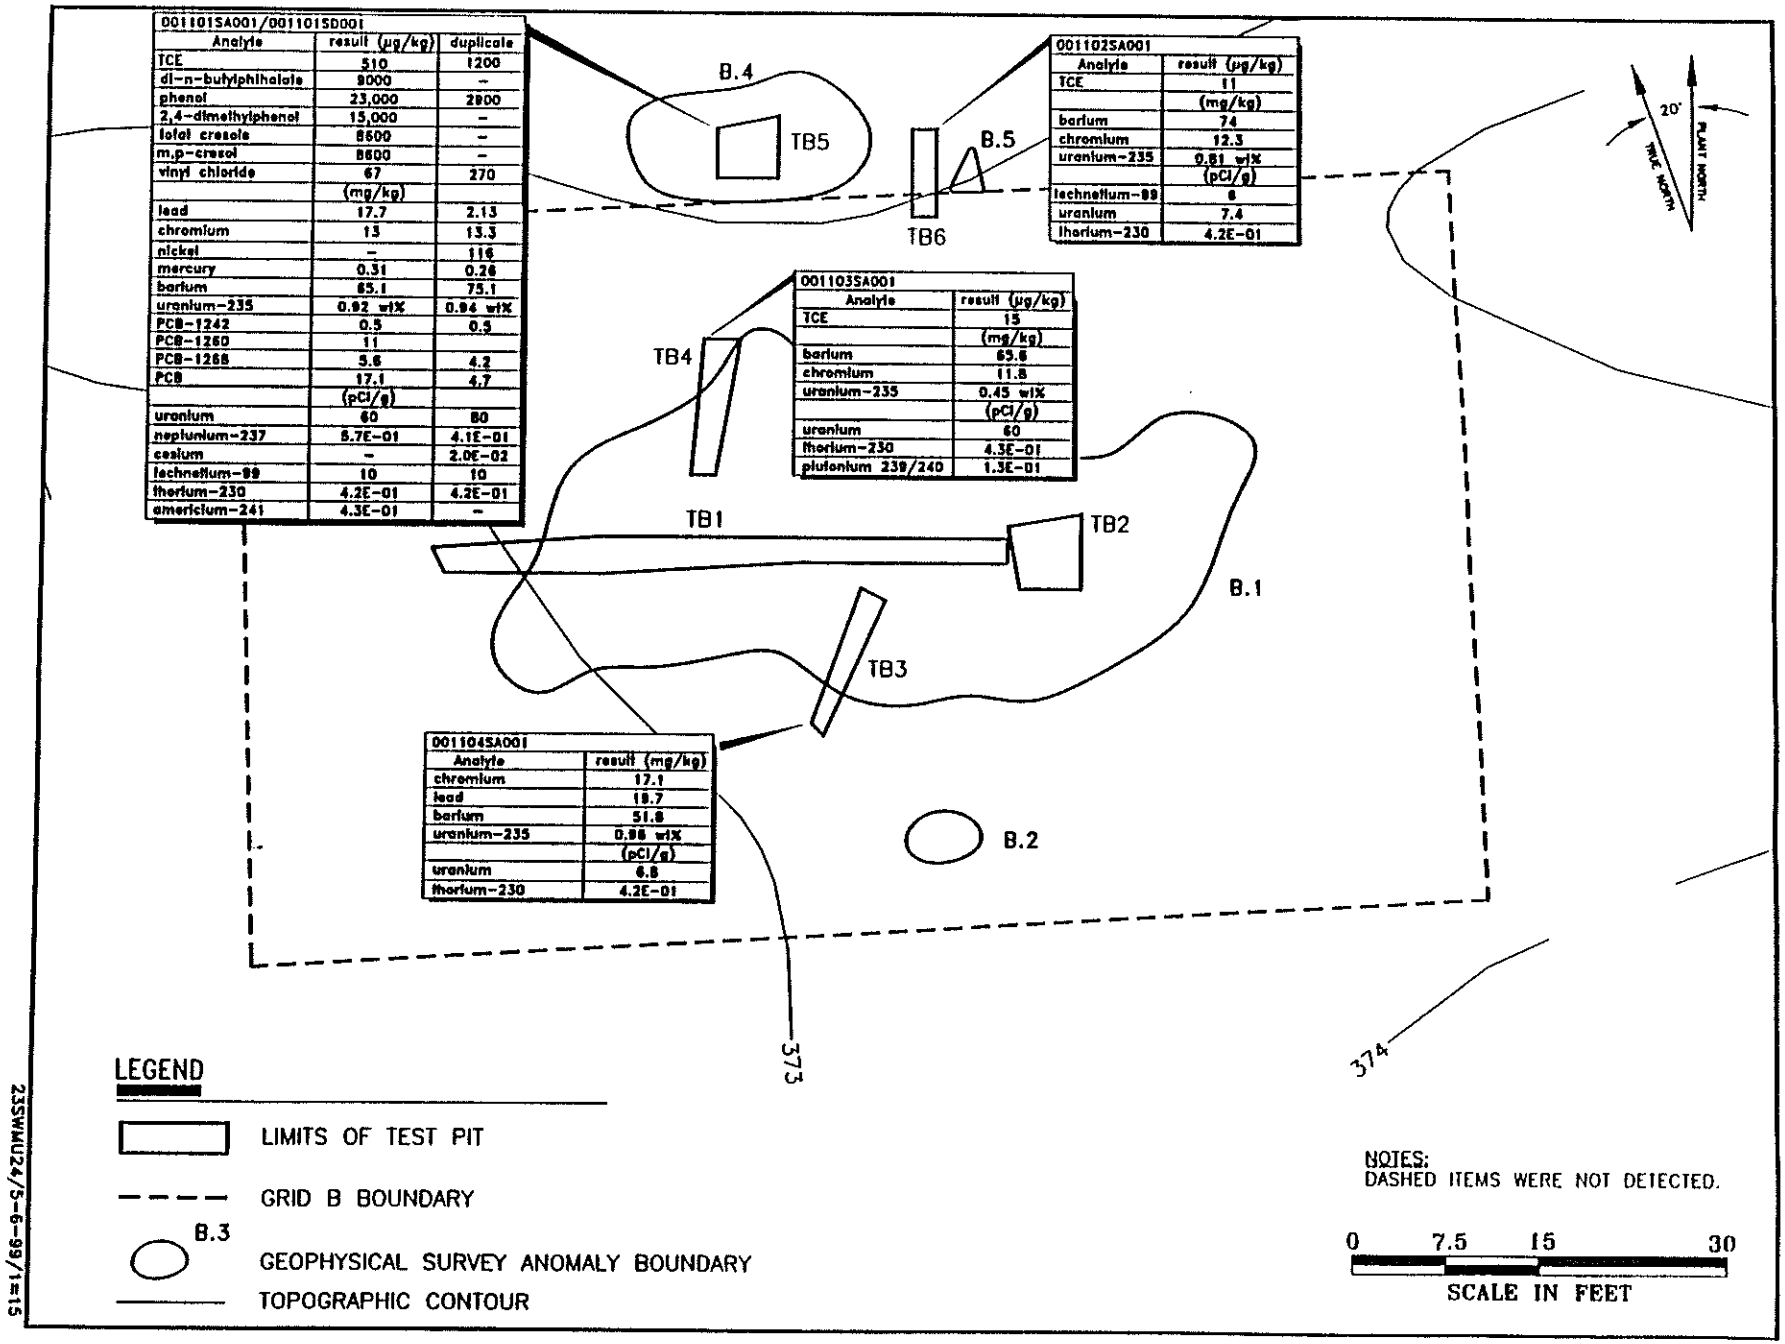

Fig. 3.3. Analytical results for soil samples at Grid B (positive detections only)

Table 3.1. Rationale for location of test pits at SWMU 1—WAG 27

Test pit number	Rationale	Comments
TB-1	Located in center of magnetometer maxima at west end of anomaly. Expanded through long axis of largest anomaly.	Uncovered drum rings, rags, gloves, some asphalt or coal, and alumina pellets. Tube of grease uncovered near TB-1 location. PID 0 ppm GM <200 cpm
TB-2	Located at eastern geophysical maxima of largest anomaly.	Uncovered five drum lids and small, white pellets (alumina trap material). Insignificant PID/GM readings
TB-3	Located to determine the southern boundary of largest anomaly and the extent of former landfarm trench.	Determined edge of former trench corresponded well with edge of anomaly. PID <5 ppm GM <200 cpm (background 100 cpm) Sample # 001104SA001
TB-4	Located to verify the extent of landfarm trench as determined by magnetometer anomaly.	Clearly determined the edge of landfarm trench. Excellent correlation with edge as defined by magnetometer survey. PID <5 ppm GM 2000 cpm at edge of former trench. Sample # 001103SA001 collected
TB-5	Centered in small anomaly to determine presence or absence of metallic object(s).	No metal discovered. Re-excavated on 1/30/98 to collect sample at area of high PID/GM readings. PID >100 ppm GM 1000 cpm Sample # 001101SA001 001101SD001
TB-6	Located along northern boundary of Grid B between TB-5 and smaller anomaly to the east to confirm presumed extent of former landfarm trench.	No metal discovered. Confirmed former landfarm trench extended through the area. PID 5 ppm GM 18,000 cpm Sample # 001102SA001
TA-1	Investigated long axis of Grid A anomaly.	Encountered 18-in. concrete (storm water?) pipe. Test pit extended along pipe. No PID or GM readings above background.
TA-2	Designed to investigate limits of anomaly.	Not excavated—determined to be unnecessary after TA-1 was extended.
TA-3	Investigated maximum magnetometer reading in Grid A.	Several pieces of carbon steel piping and/or steel plate at ~0.5 ft. No evidence of landfarm trenches. No readings above background with PID or GM.

Table 3.2. Summary of analytical samples collected for SWMU 1 test pits

Sample ID	Date/time	Analytical requirements	COC no.	Description
001101SA001	1-30-98 1130	VOCs, SVOCs, metals, PCBs, and full rad*	WAG23-030	Soil sample from SWMU 1 test pit (TB-5). Grid B.
001101SD001 (duplicate)	1-30-98 1145	VOCs, SVOCs, metals, PCBs, and full rad*	WAG23-030	Duplicate soil sample from SWMU 1 test pit (TB-5). Grid B.
001101SA002	1-28-98 1217	VOCs	WAG23-030	Trip blank for sample 001101SA001, 001101SD001, 001102SA001, 001103SA001, and 001104SA001.
001102SA001	1-30-98 1055	VOCs, SVOCs, metals, PCBs, and full rad*	WAG23-030	Soil sample from SWMU 1 test pit (TB-6). Grid B.
001103SA001	1-29-98 0859	VOCs, SVOCs, metals, PCBs, and full rad*	WAG23-030	Soil sample from SWMU 1 test pit (TB-4). Grid B.
001104SA001	1-29-98 1240	VOCs, SVOCs, metals, PCBs, and full rad*	WAG23-030	Soil sample from SWMU 1 test pit (TB-3). Grid B.
001000NR001	2-5-98 1650	VOCs, SVOCs, PCBs, metals, and full rad*	WAG23-031	Equipment rinseate sample for SWMU 1 test pits.
001000NR002	2-2-98 1100	VOCs	WAG23-030	Trip blank for sample 0011000NR001.

* Full rad consists of ^{60}Co, ^{235}U, ^{99}Tc, ^{239}Pu, ^{241}Am, ^{237}Np, ^{230}Th, ^{137}Cs, and uranium.

Test pit TB-2 was placed in the approximate center of the largest magnetic anomaly in Grid B. Five metal drum lids were unearthed in this pit, along with numerous small, white pellets. A grab sample of the pellets was collected and sent to the C-710 laboratory for analysis for uranium assay. The drum lids were found within 2 to 3 ft of one another at a depth of 0.5 ft. The pit was extended below the drum lids to a depth of 1.5 to 2.0 ft and extended laterally to confirm that no other metallic objects were present. A layer of crushed stone was encountered at the bottom of the excavation along with pieces of wood and some plastic tubing. Field instrumentation recorded little evidence of contamination. Final dimensions of TB-2 were approximately 4 ft by 5 ft by 3.5 ft. The pit was backfilled with native material.

TB-4 was excavated to verify the northern extent of the largest magnetic anomaly. The excavation uncovered a distinct interval of sand used during landfarm activities that allowed an accurate determination of the margins of the former landfarm. The extent of landfarm material corresponded very well with the edges of the magnetic anomaly. No metallic objects were found. No organic vapors were detected but the radiologic meter detected up to 2000 cpm in a layer of crushed stone at the base of the pit. TB-4 measured 2 ft by 10 ft by 3 ft. The pit area was marked as a radiological area and backfilled with the excavated material.

TB-1 was excavated as an elongate trench to encompass the long axis of the largest magnetic anomaly. The trench was excavated to the top of the gravel layer (2 to 3 ft) found in other test pits that presumably lined the bottom of the original landfarm area. Depth to the gravel layer increased from east to west. Alumina pellets, two drum rings, rags, gloves, and some pieces of asphalt or coal were unearthed in TB-1 at a depth of approximately 1 ft (± 0.5 ft). One of the drum rings was found directly below the highest reading on the EM-61. Some purple soil discoloration was observed on the trench walls. Physical evidence (i.e., crushed stone and soil discoloration) suggested the former oil landfarm trench extended beyond the magnetic anomaly. No organic vapors were detected and the radiologic meter detected <200 cpm in TB-1.

TB-3 was to determine the southern margin of the former oil landfarm. The pit was begun within the region of the anomaly and extended south until the edge of the former landfarm was discerned. The edge of the landfarm trench was determined to be approximately 3 ft south of the edge of the magnetic anomaly. TB-3 encountered brown to grey-brown sandy fill to 2–2.5 ft, where an interval (6 to 8 in.) of #3 crushed stone was encountered, underlain by mottled orange and grey silt. No metallic objects were recovered. Field monitoring instruments detected no organic vapors (<5 ppm) and radiological readings (200 cpm) were slightly above background (100 cpm). This area did not require posting as a radiologic area as determined by PGDP health physics personnel.

TB-6 was excavated to determine the extent of a suspected landfarm trench defined by three small anomalies detected north of Grid B and encountered at TB-5. The test pit encountered brown to grey-brown sand fill to a depth of 2.5 ft, underlain by 0.5 to 1 ft of #3 crushed stone, then blue-grey silt at the base. Organic vapors were detected up to 5 ppm and radiological activity up to 18,000 cpm were detected. This area was marked as a radiological area and backfilled with excavated material.

3.4 GRID A INVESTIGATION

Three test pits were planned within Grid A to investigate an anomaly detected during the site investigation. The anomaly was corroborated by the magnetometer survey conducted during this investigation, and found to be smaller than the largest anomaly in Grid B. Test pit TA-3 was excavated first, followed by TA-1. Test pit TA-2 was not necessary because TA-1 was extended to

cover most of the anomaly. Field screening instrumentation recorded no readings above background in either test pit and no samples were collected.

Several pieces of carbon steel piping and/or steel plate were uncovered in TA-3 at a depth of 2 ft. No other material was discovered. It is believed these small pieces of piping comprised the anomaly. No evidence of the landfarm was noted in TA-3 and no readings above background were recorded.

A large (18 in.) diameter concrete pipe along the axis of the magnetic anomaly was uncovered in TA-1. The line was not included on any PGDP utility maps. The approximate dimensions of the line were determined by probing with the excavating equipment and with a hand probe. The ends of the line were surveyed to determine the slope of the pipe. The survey determined the line dropped 1ft over 24 ft (0.042 ft/ft).

3.5 ANALYTICAL RESULTS FOR SWMU 1 TEST PIT SAMPLES

Analytical data from soils collected from the test pits suggest the former Oil Landfarm may contribute to groundwater contamination at PGDP. VOCs, SVOCs, PCBs, metals, and radionuclides were detected in the soil samples. Soil from test pit TB-5 contained the largest number of contaminants in the highest concentrations and was the only location that included SVOCs and PCBs. Other test pits contained low concentrations of VOCs, metals, and radionuclides. Figure 3.3 presents the distribution of contaminants detected in the analytical samples at SWMU 1.

Contamination from past disposal practices is evident in test pit TB-5. The soil sample (001101SA001) contained elevated concentrations of SVOCs including phenol (23,000 µg/kg), 2,4-dimethylphenol (15,000 µg/kg), di-n-butylphthalate (9000 µg/kg), and cresol (8600 µg/kg). PCB concentrations totaled 17.1 µg/kg. Two VOCs were detected: trichloroethene was detected at a concentration of 510 µg/kg and vinyl chloride at 67 µg/kg. Inorganics include barium (65.1 mg/kg), chromium (13 mg/kg), lead (17.7 mg/kg), and mercury (0.31 mg/kg). Radionuclides detected include uranium (67 pCi/g), ^{235}U (0.92 weight %), ^{237}Np (0.57 pCi/g), ^{99}Tc (10 pCi/g), ^{230}Th (0.42 pCi/g), and ^{241}Am (0.43 pCi/g). The duplicate sample contained similar contaminants at different concentrations, including phenol at 2900 µg/kg, but no other SVOCs. TCE was detected at a concentration of 1200 µg/kg and vinyl chloride at 270 µg/kg. Nickel was detected in the duplicate (but not in the original sample) at a concentration of 116 mg/kg.

Other test pits indicated few contaminants. TCE was detected in TB-6 (11 µg/kg) and TB-4 (15 µg/kg), but no other organics were detected. Barium and chromium were detected in TB-3, TB-4, and TB-6, with lead also detected in TB-3. Concentrations of these metals were all below 100 mg/kg. Radionuclides were detected in all samples. The highest concentrations were detected in TB-4, where uranium was detected at 63 pCi/g.

Whitish granular material or pellets uncovered at the former Oil Landfarm were sampled and analyzed by LMES. Results of these analyses revealed the material contained 295 pCi/g total uranium assayed at 1.062 wt% ^{235}U. The remainder of the material was largely alumina with other metals and silica. It is speculated the material was included in oil contaminated with alumina from the C-720 Instrument Shop (LMES 1998). A detailed discussion relating to the origin of the alumina uncovered during the excavation activities is included as Appendix D of this report.

4. EXCAVATIONS AT BUILDING C-746-A SEPTIC SYSTEM

Excavation activity at the C-746 area was necessary to uncover the septic tanks lids to facilitate sampling of the tank contents. Sampling is required at these tanks to confirm or deny their contents as sources of contamination. The tanks are recognized as a potential source of heavy metal and radiological contaminants.

4.1 NORTHEAST SEPTIC TANK

The septic tank at the northeast corner of Building C-746-A was excavated first, using a Case 580L backhoe. PGDP construction drawings indicate the tank dimensions at 84-in. by 66-in. by 44-in. The top of the tank was located approximately 1.5 to 1.8 ft bgs. The excavation uncovered two access ports on the top of the tank measuring 2 ft by 2 ft.

LMUS Chemical Operations (Chem Ops) removed the contents of the northeast Building C-746-A septic tank. The tank contained approximately 10 in. to 12 in. of liquid above the sludge at the bottom. A vacuum truck was used to remove the contents of the sump and pump the contents into 55-gal drums. Each drum used in these removals was fitted with a sorbent pad and a 10-mil plastic liner. A layer (1–2 lb) of absorbent material was placed in the bottom of each drum prior to filling, and additional absorbent material was added as the drum was filled. The sludge was largely saturated and appeared dark black and viscous.

Eleven drums of material were removed from the northeastern septic tank. Drums for this septic tank material were labeled #58514-01 through #58514-11. One drum of PPE was also collected and identified as #58516. The empty septic tank was abandoned by backfilling it with clean sand, and then grading the site at the surface.

4.2 NORTHWESTERN SEPTIC TANK

The septic tank at the northwestern corner of Building C-746-A was reported to be a 5-ft-diameter concrete tank. However, the excavation uncovered a 5-ft-diameter corroded steel tank at a depth of approximately 2.5 ft below ground surface. The tank cover contained several holes and was full of water. No organic vapors or radioactivity was detected with field instrumentation.

Since no access ports were found on the tank cover, the top of the tank was removed with a backhoe to facilitate sampling. Chem Ops personnel removed the contents of the tank with a vacuum truck. Tank contents were placed in 55-gal drums. The material (liquid and sludge) was placed in 55-gal drums and mixed with chemical absorbent to remove liquids. A total of ten 55-gal drums were filled with material from the C-746-A northwest tank. Three drums were filled with liquid, and the remaining seven with a mixture of sludge and liquid. None of the sludge exhibited organic vapors or radiological activity when screened with field instruments. The empty northwest tank was abandoned by backfilling it with clean sand, and then grading the site.

4.3 SLUDGE SAMPLE COLLECTION

Grab samples of sludge from 6 of the 21 drums filled during the investigation were collected and analyzed to characterize the material. A decontaminated stainless steel spoon was used to collect each sample in accordance with Paducah EMEF procedures PTSA-4201 and PTWM-5500 "Sampling of Containerized Waste." Samples were collected in appropriate containers for analyses for PCBs, metals, radionuclides, asbestos, and paint-filter test and transported to the LMUS analytical laboratory in Building C-710. Proper sample custody was maintained at all times. Table 4.1 summarizes the pertinent information for the sludge, waste characterization, and QC samples collected during the sludge removal operations.

4.4 ANALYTICAL RESULTS FOR C-746-A SEPTIC TANK SLUDGE SAMPLES

Analyses of six samples of the material removed from the septic tanks indicated metals were the only analyte detected. Metals were the only constituent detected in the samples. Results of these analyses are summarized on Fig. 4.1. Samples from the northeast tank contained (as maxima of three samples) barium (45 mg/kg), lead (22.6mg/kg), and nickel (326 mg/kg). Metals detected in the sludge from the west tank included barium (35.2 mg/kg), lead (55.1 mg/kg), nickel (78.1 mg/kg), and selenium (4.82 mg/kg).

4.5 DATA REVIEW, VALIDATION, AND ASSESSMENT

Analytical results were forwarded to the LMES Sample Manager. These data were electronically entered into the PGDP Project Environmental Measurement System (PEMS) database by the LMES Sample Manager. These data were be entered into the Paducah Oak Ridge Environmental Information System upon completion of the project. Analytical results are summarized in Appendix C.

Data were contractually screened, verified, validated, and assessed by LMES according to PMSA-1001 "Quality Assured Data." Contractual screening is designed to determine if all required documentation is intact as required for the proper analyses. Contractual screening includes (1) data delivery tracking and costing and (2) review of sample identification, signed chain-of-custody, required turnaround time, and verification (holding time, units, and either criteria as applicable).

Validation procedures were conducted to screen the data against known criteria according to U.S. Environmental Protection Agency and LMES procedures. LMES procedures employed include ERWM/ER-P2209, "Radiochemical Data Verification and Validation"; ERWM/ER-P2211, "Pesticide and PCB Data Verification and Validation"; and ERWM/ER-P2210, "Inorganic Data Verification and Validation." No problems were encountered with the data for this project.

The data assessment process, conducted after the completion of data verification and validation, is performed to determine if the total set of environmental measurements data satisfies the requirements of the project data quality objectives (DQOs). Parameters reviewed during the data assessment process include sensitivity, precision, accuracy, representativeness, completeness, and comparability. The data assessment was completed in accordance with PMSA-1001, "Quality Assured Data". Data assessment results indicated that the data are precise, accurate, complete, comparable, and representative and met the project DQO's.

Table 4.1. Summary of analytical samples collected for C-746-A septic tanks.

Sample ID	Date/time	Analytical requirements	COC no.	Description
196001SA001	2-4-98 1340	PCBs, metals, asbestos, paint filter test, and full rad*	WAG23-033	Sludge sample from drum 58513-01 (west end septic tank at C-746-A).
196001SD001 (duplicate)	2-4-98 1350	PCBs, metals, asbestos, paint filter test, and full rad*	WAG23-033	Duplicate sludge sample from drum 58513-01 (west end septic tank at C-746-A).
196002SA001	2-4-98 1520	PCBs, metals, asbestos, paint filter test, and full rad*	WAG23-033	Sludge sample from drum 58514-08 (east end septic tank at C-746-A).
196003SA001	2-4-98 1405	PCBs, metals, asbestos, paint filter test, and full rad*	WAG23-033	Sludge sample from drum 58513-03 (west end septic tank at C-746-A).
196004SA001	2-4-98 1455	PCBs, metals, asbestos, paint filter test, and full rad*	WAG23-033	Sludge sample from drum 58514-04 (east end septic tank at C-746-A).
196005SA001	2-4-98 1415	PCBs, metals, asbestos, paint filter test, and full rad*	WAG23-033	Sludge sample from drum 58513-05 (west end septic tank at C-746-A).
196006SA001	2-4-98 1510	PCBs, metals, asbestos, paint filter test, and full rad*	WAG23-033	Sludge sample from drum 58514-06 (east end septic tank at C-746-A).
196000ND001	2-6-98 1530	VOCs, PCBs, metals, gross alpha/beta, oil and grease, ^{99}Tc, gamma spec, and total suspended solids	WAG23-036	Waste characterization sample of decon water used for SWMU 1 test pits and C-746-A septic tanks.
196000ND002	2-6-98 1230	VOCs	WAG23-036	Trip blank for sample 196000ND001.

* Full rad consists of ^{60}Co, ^{235}U, ^{99}Tc, ^{239}Pu, ^{241}Am, ^{237}Np, ^{230}Th, ^{137}Cs, and uranium.

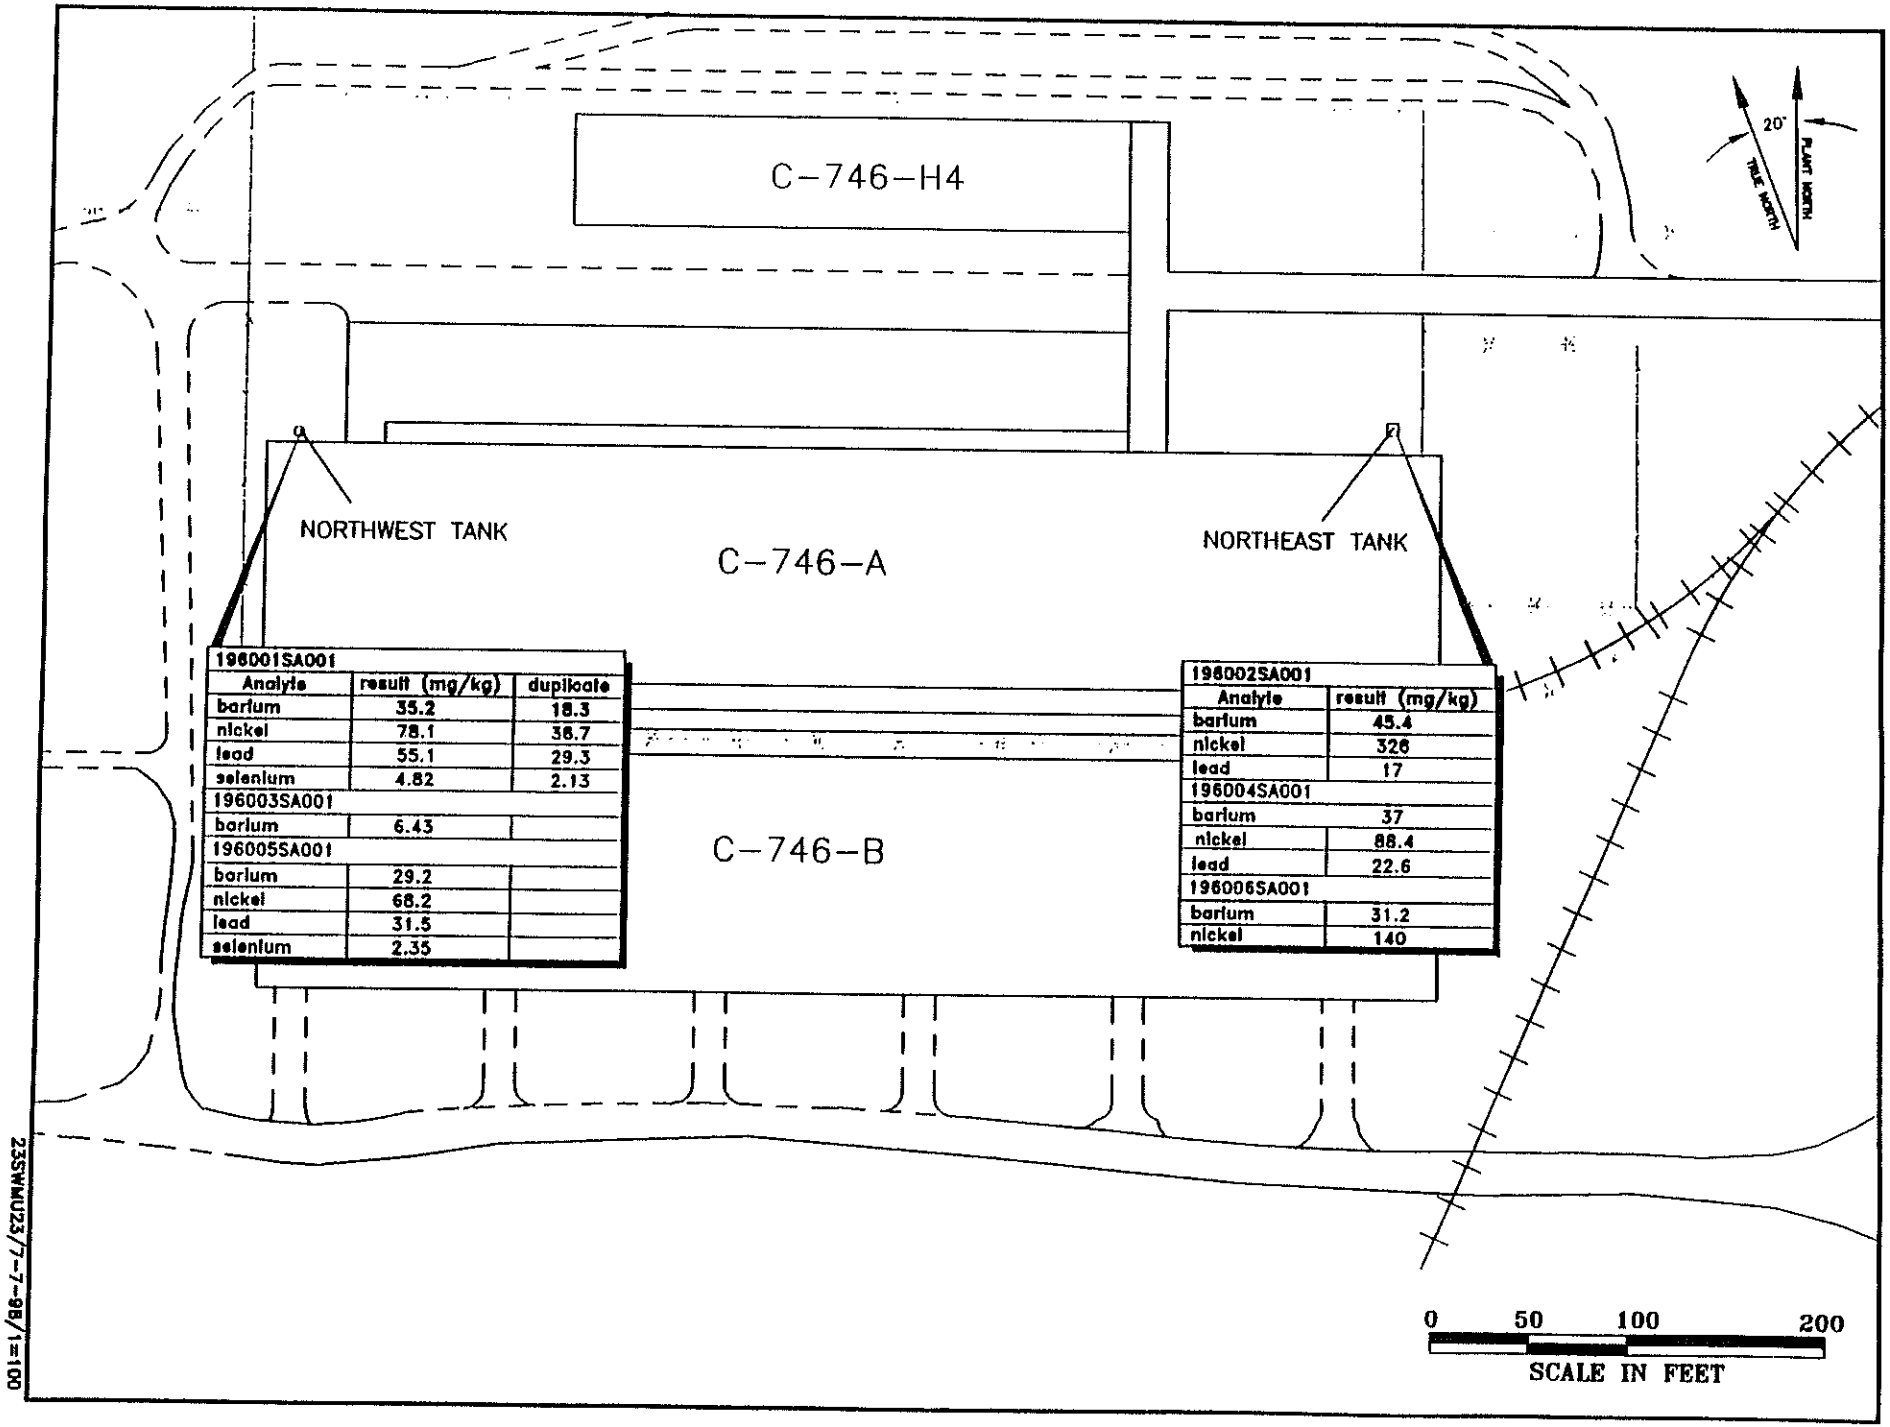

Fig. 4.1. Analytical results for sludge samples at C-746-A septic tanks (positive detections only)

5. SUMMARY OF FINDINGS

A geophysical survey and a series of excavations were conducted at WAG 27 to investigate potential contaminant source areas within the former C-747-C Oil Landfarm (SWMU 1) and Building C-746 area of PGDP. These activities were part of the ongoing RI for WAG 27.

The geophysical survey was designed to guide the excavation of test pits within SWMU 1. The survey used a EM-61 magnetometer to clearly define the boundaries of magnetic anomalies. Magnetometer readings were obtained along a closely spaced grid, then augmented by continuous readings to define the perimeter of magnetic anomalies. The survey discovered one large and numerous smaller anomalies.

A series of test pits were excavated at the magnetic anomalies to determine if the anomalies contained material that may represent a source of contamination. Test pits at SWMU 1 uncovered no large metallic objects such as drums. Magnetic anomalies in Grid B were probably caused by small items (e.g., drum lids, drum bungs, metal shavings in waste oil) and/or residual metals from oils disposed in the landfarm. The magnetic anomalies at Grid B closely defined two roughly parallel landfarm trenches that were confirmed by the test pits. This suggests that residual metals in the former Oil Landfarm left a magnetic signature in the vicinity of the disposal trenches. Small metal items discarded in the trenches produced smaller anomalies and local maxima within the larger anomaly.

The anomaly in Grid A was caused by a large concrete drain pipe. The EM-61 can detect large nonmetallic objects, such as uncovered in Grid A. The source and purpose of this pipe are unknown, but the pipe does not appear to have contributed to groundwater contamination.

Sludge samples from the C-746-A septic tanks reveal they are probably not a source of contamination for the groundwater plumes at PGDP. The northeast tank contained sludge and liquid and was found intact and half full. Material in the tank was removed, placed in drums with absorbent material, and sampled. The tank was then abandoned in place by backfilling it with clean sand. The northwest tank was found to be of steel construction which was corroded, in poor condition, and completely full. The top of the tank was removed to allow access to the material in the tank. The northwest tank also contained fluid and sludge. The material was removed and placed in drums, and the tank was backfilled and abandoned in place.

Analytical results suggest the former Oil Landfarm may be a source of off-site goundwater contamination at PGDP. The presence of organic vapors with residual TCE and vinyl chloride in the soil in TB-5 suggest a release occurred in the vicinity of the test pit. Lower concentrations of TCE in adjacent test pits may be associated with this release. Radionuclides detected in the vicinity suggests past disposal practices may have included contaminated oils. This is substantiated by the presence of contaminated alumina pellets.

The C-746-A septic system does not appear to be a source of residual contamination. Metals detected in the sludge are consistent with past usage of Building C-746-A as a smelting operation. Concentrations of metals were not sufficiently elevated to suggest the septic system was a source of any large releases to the environment. The lack of any residual organic contaminants suggests that

solvents were not disposed in the septic system. The septic system should be removed from any further consideration as a source of contamination.

Appendix D

ANALYSIS OF THE DEPOSITS IN THE C-747-C OIL LANDFARM

ANALYSIS OF THE DEPOSITS IN THE C-747-C OIL LANDFARM

Introduction

On Thursday, January 29, 1998, a subcontractor working on the Waste Area Grouping (WAG) 23/27 Removal Action uncovered several test pits at the former oil landfarm at the C-747-C facility. A deposit of particular interest was found at three sites. The granular material was analyzed to contain 295 pCi/g total uranium at an assay of 1.062 wt% ^{235}U. Analytical results confirm the material to be alumina contaminated predominantly with metals and silica.

Looking at the analyses and the parameters associated with the deposits at the oil landfarm, two situations were evaluated to determine the most likely source pathway: from large alumina traps in the cascade or from smaller traps associated with sample streams.

Following that review, bounding calculations were performed to determine if further Nuclear Criticality Safety (NCS) controls are indicated. Order of magnitude comparisons were also made to the threshold quantities of 40 CFR 302.4 to determine if further safety documentation is required.

Large Cascade Traps

Alumina is used for trapping low to moderate concentrations of uranium compounds (predominantly UF_6) in gas streams from the cascade enrichment facilities. Alumina is used in seal exhaust traps to remove the uranium compounds present in the exhaust stream prior to discharge to the atmosphere. At times, moderate concentrations are present in the seal exhaust stream due to compressor seal failure. When the alumina becomes saturated, it is removed in-situ from the trap and placed in drums. If the contaminated alumina comes from a seal exhaust system located where the uranium is enriched to greater than 1.0 wt% ^{235}U, movement of the drums is strictly controlled under a NCS Approval (NCSA).

Alumina is also is used in wet air traps to remove uranium compounds from purge gases prior to discharge to the atmosphere. Low concentrations are generated during activities associated with enrichment cell servicing. As with the seal exhaust traps, when the alumina is sufficiently saturated, it is removed into drums in-situ. If the alumina from a wet air trap is contaminated with fissionable assay uranium, it is strictly handled in accordance with applicable NCSAs.

Since the assay of the landfarm deposit was found to be greater than 1.0 but less than 2.0 wt% ^{235}U, the trap mix would most likely have come from either an 18-inch or a 24-inch diameter trap.

The 18-inch diameter traps, used at C-310, C-331, and C-333 for purge gas and wet air evacuation, were fabricated from 18-inch schedule 10 pipe with an overall length of 6.5 feet. The volume occupied by the alumina was slightly less than 8.0 cubic feet. Assuming a bulk density of not greater than 55 pounds for alumina and a maximum accumulation constant of one pound of UF_6 per pound of alumina, a trap is assumed to contain approximately 298 pounds uranium for NCS purposes.[1] Since the volume of the trap exceeds the volume of a 55-gallon

drum, the alumina was usually placed in equal amounts in two drums. If the material was of fissionable assay, Chemical Operations would have transported this material to storage in a safe array. Also, since the assay was greater than 0.5 wt% ^{235}U (the threshold for an economically recoverable material), it would have been shipped off-site for recovery.

The 24-inch diameter traps, used at C-331, C-333, C-335, and C-337 in seal exhaust systems, contain approximately 13.2 cubic feet which, at the parameters assumed above, would yield a total of 490 pounds of uranium.[1] This material would fill two 55-gallon drums but could have been distributed equally into three. If this material was of fissionable assay, it too would have been stored in a safe array until final disposition.

In either case, a drum of material would have contained a maximum of 285 pounds of uranium which is safe in a 55-gallon drums when spaced appropriately.[1] This assessment is conservative when compared to actual experience. The average weight of contaminated alumina from all the traps measured historically is actually 121% the charged weight of alumina and the loading experienced to date seldom, if ever, exceeds 150%.[1]

Normally the traps are serviced in-place in their installed configuration. Multiple failures in the system could contaminate the alumina with oil. It is doubtful that the material would have been contaminated to the extent that the material would have been taken to the landfarm. If the uranium compounds had "broken through" to the vacuum pump, the oil would have thickened to the point of pump failure. This material would have been removed at the vacuum pump service shop in either C-720 or C-400; however, it would not have contained large amounts of alumina as observed in the landfarm.

The hydrocarbon oil from large vacuum pumps will absorb a maximum of 4.5 pounds of UF_6 per gallon. Consequently, if this oil is contaminated with fissionable assay uranium, its movement, storage, and disposition is also controlled strictly by NCSA to maintain a safe array. Consolidation of the contents of drums contaminated with fissionable assay uranium is prohibited.

The uranium activity in the landfarm sample indicates that it is 150 to 435 times less concentrated than would be expected from the spent material removed from a large cascade trap. (See calculations below.)

Small Sampling Traps

Alumina is also found in smaller traps on sample buggies or assay machines. The size may range from 2 to 6 inches in diameter and up to 18 inches in length. These traps are usually installed in conjunction with small vacuum pumps called "rough pumps" which remove uranium compounds from extremely dilute sample streams. These pumps were serviced in the C-720 Instrument Shop. It is conceivable that the used oil and small amounts of contaminated alumina were accumulated in a single drum since the dilute concentrations required no special NCS controls at any assay. The concentration of uranium in the waste material would be commensurate with that observed in the land farm. It is also conceivable that this material would be selected for disposal in the landfarm.

The negligible uranium concentration is the reason that these drums were not treated with the same NCS controls as alumina from the larger traps. Also, the alumina from the small traps would appear as clumps contaminating the drum of oil instead of oil contaminating a drum of alumina as might be possible given the "break through" failure of a large trap.

Landfarm Deposit Parameters

The volume of a single pocket of alumina (5.5 cubic feet) indicates that was probably poured from a 55-gallon drum. The pellet-like appearance is consistent with the form of alumina used in charging traps at the plant. The assay of the deposit indicates that the alumina was used to trap fissionable assay gas streams. Either the large or the small traps could have be exposed to the 1.1 wt% assay as analyzed for the deposit.

It is possible, but not probable, that alumina taken from large cascade traps would have inadvertently be placed in the landfarm. However, due to the criticality controls and recoverable value, the likelihood is remote. The activity of the sample, 295 pCi/g, indicates a uranium concentration much less than would be predicted by historical data.

Calculations using guidance from DOE 5480.24 and the ANSI/ANS 8 Series, indicates that approximately 170,000 pounds of the deposit material at the measured assay and concentration would be required to exceed the 700 g ^{235}U threshold for NCS controls. Estimates predict that there is less than 50 cubic feet of the trap material in the three deposits; providing an ample margin of safety. Conservatively assuming that the deposit is trap mix loaded with an equivalent amount of UF_6, there would be approximately 5400 pounds in the three deposits.

DOE-EM-STD-5502-94 requires safety analysis documentation for all facilities having quantities of nuclear or non-nuclear materials exceeding the threshold amounts cited in 40 CFR 302.4. Using the same assumed density for the deposit and the analyzed activity, the calculated amount of total uranium in the oil landfarm would be 0.000729 Ci. This is far less than the threshold quantity of 0.1 Ci established for the uranuium nuclides present in 40 CFR 302.4.

Conclusion

The size and the activity of the deposits indicate that the source of the material uncovered is from accumulation of oil contaminated with alumina from the C-720 Instrument Shop. Calculations show that there is insufficient quantities of uranium contamination to warrant NCS controls, even at the assay measured. Since the threshold quantity cited by 40 CFR 302.4 is not challenged, no further safety documentation would be required.

CALCULATIONS

Predicted activity from a drum of alumina from a large trap

If an 18-inch diameter trap is emptied equally into two drums, the total uranium content assuming an average 121% loading would be-

$$\frac{4\ ft^3 \times 55\ lb/ft^3 \times 21\% \times 238\ lb\ U}{352\ lb\ UF_6} = \mathbf{31.2\ lb\ or\ 14{,}200\ gU}$$

Assuming all activity in the drum is due to ^{235}U and ^{238}U, the activity produced at an assay of 1.1 wt% is-

$$\frac{0.011\ g^{235}U}{gU} \times \frac{14{,}200\ gU}{} \times \frac{2.16\times10^{-6}\ Ci}{g^{235}U} = \mathbf{3.37\times10^{-4}\ Ci}$$

$$\frac{0.989\ g^{238}U}{gU} \times \frac{14{,}200\ gU}{} \times \frac{3.36\times10^{-7}\ Ci}{g^{238}U} = \mathbf{4.72\times10^{-3}\ Ci}$$

3.37×10^{-4} Ci + 4.72×10^{-3} Ci = **5.09×10^{-3} Ci total activity**

Since the alumina charged weighs 100,000 g, the activity by weight for this lower bounding condition would be-

5.09×10^{-3} Ci / 114,000 g = **4.46×10^{-8} Ci/g**

If a 24-inch diameter trap is emptied equally into two drums, the total uranium content assuming a maximum 150% loading would be-

$$\frac{6.6\ ft^3 \times 55\ lb/ft^3 \times 50\% \times 238\ lb\ U}{352\ lb\ UF_6} = \mathbf{123\ lb\ or\ 55{,}700\ gU}$$

Assuming all activity in the drum is due to ^{235}U and ^{238}U, the activity produced at an assay of 1.1 wt% is-

$$\frac{0.011\ g^{235}U}{gU} \times \frac{55{,}700\ gU}{} \times \frac{2.16\times10^{-6}\ Ci}{g^{235}U} = \mathbf{1.32\times10^{-3}\ Ci}$$

$$\frac{0.989\ g^{238}U}{gU} \times \frac{55{,}700\ gU}{} \times \frac{3.36\times10^{-7}\ Ci}{g^{238}U} = \mathbf{1.85\times10^{-2}\ Ci}$$

1.32×10^{-3} Ci + 1.85×10^{-2} Ci = **2.00×10^{-2} Ci total activity**

Since the alumina charged weighs 100,000 g, the activity by weight for this upper bounding condition would be-

2.00×10^{-2} Ci / 155,000 g = **1.29×10^{-7} Ci/g**

The activity of the deposit was analyzed to be **2.95×10^{-10} Ci/g.** This activity is a factor of 150 to 435 times lower than the bounding conditions evaluated in the above calculations.

Determination of mass of alumina required for implementation of NCS controls

Assuming all activity in the deposit is due to ^{235}U and ^{238}U, 1.0 g of material at an assay of 1.1 wt% ^{235}U would produce a total activity of-

$0.011\ g \times 2.16\times10^{-6}\ Ci/g = \mathbf{2.38\times10^{-8}\ Ci}$ **due to** ^{235}U

$0.989\ G \times 3.36\times10^{-7}\ Ci/g = \mathbf{3.36\times10^{-7}\ Ci}$ **due to** ^{238}U

$3.36\times10^{-7}\ Ci + 2.38\times10^{-8}\ Ci = \mathbf{3.60\times10^{-7}\ Ci}$ **per gram total**

The activity at 1.1 wt% ^{235}U due to the ^{235}U isotope alone would be-

$2.38\times10^{-8}\ Ci / 3.60\times10^{-7}\ Ci =$ **0.066 of the total activity**

If the activity of the sample from the deposit is 295×10^{-12} Ci/g, then the activity due to ^{235}U is-

$0.066 \times 295\times10^{-12}\ Ci/g = \mathbf{1.95\times10^{-11}\ Ci/g}$

With optimum configuration, moderation, and reflection, greater than 700 g ^{235}U is required for criticality, this corresponds to an activity of-

$700\ g \times 2.16\times10^{-6}\ Ci/g = \mathbf{1.51\times10^{-3}\ Ci}$ ^{235}U **for criticality**

The mass of the deposit required to produce an activity equivalent to 700 g ^{235}U at the sample assay and activity is-

$1.51\times10^{-3}\ Ci / 1.95\times10^{-11}\ Ci/g = \mathbf{7.74\times10^{7}\ g\ or\ 170{,}000\ lb}$

Assuming a 200% loading of the trap material, the conservative mass of the three deposits is-

$110\ lb/ft^3 \times 49.5\ ft^3 =$ **5400 lb**

Since there is an undetermined activity in the sample due to ^{234}U, the actual fraction of activity in the sample due to ^{235}U would actually be less: thus, making the above calculations conservative.

Comparison of predicted quantities of uranium to 40 CFR 302.4 thresholds

Assuming a 200% loading of the trap material, the total activity due to uranium is-

$$\frac{110\ lb}{ft^3} \times \frac{49.5\ ft^3}{} \times \frac{454\ g}{lb} \times \frac{2.95\times10^{-10}\ Ci}{g} = \mathbf{7.29\times10^{-4}\ Ci}$$

This compares with **0.1 Ci** established for the uranium nuclides present.
